You might want to think about a W9INN - Hand built and individually
tuned to your location for 80, 40, 20, 15, and 10M - No tuner required -
87 ft long - Mount flat top or Inverted V - I like mine...

http://www.cableone.net/ctj92/index.html?row1col2=w9inn.html

Source record: 151789

Hi, I live in an area where the term "Quiet rotor" is referred to in the zoning ord. It's a quiet suburban subdivision. A guy in the neighborhood mentioned he could hear my rotor "clank" on warm nights when the windows were open. He said it in a real nasty tone (this was in front of others). I asked if it made any more noise than his kids car door slamming at 2:30 PM, loud car stereo (the kind that rattles the windows), or his own car alarm that went off so often the police had to threaten to cite him for it. It seems that the rotor brake creates much less noise that most areas have going on. BTW, the rest of the group let this guy know who was creating the real problem and he left. I'll take mine with a break.

Source record: 151790

Alpha Delta has a shortened 80-10m dipole that has loading coils for 80m only, no traps. I have one but never used it so I can't vouch for any performance.

If you use similar methods that Andrew suggests for their hard-line connectors you will have dry connectors for life. Cover the connector and several inches of cable on each side with a single layer of good electrical tape like Scotch 33+. Cover with a layer of Andrew or equivalent sticky sheet tar stuff. This usually comes in rolls 1 to 4" wide with a wax paper backing. Cover everything with several tight layers of Scotch 33+. The result will look like a black football covering the connector and cable. I have cut open many connections that were over 20yrs that have spent much of the time under water and the connectors look shiny and new. I used to skip the first layer of tape before the sticky stuff until I had to remove a connection and the sheet tar would not let go of anything. With a layer of tape under the tar you can slit the "football" with a razor knife and everything will remove easily. Look at any commercial tower or cell site and you should see nothing but footballs where cables terminate, unless hams have been there.....

6. Re: Balun/isolator for end-fed half-wave wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-01 03:23:13 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C312BA1.5A733303@eznec.com>
Source record: 151792

New Years eve seems like a good time to reminisce. . .

In about 1960 I lived in a very small duplex in Douglas, Alaska near Juneau. My room, an 8 X 12 foot bedroom shared with my older brother, was on the upper floor. (This period is immortalized in "A Ham Dirge", by John Lewallen, in August 1961 CQ Magazine.) My principal 20 meter antenna for some time was a piece of #22 enamel wire about a half wavelength long which was slammed in the window and ran out to a clothesline pole in the back. The ground sloped upward away from the house, so it was about 15 feet off the ground at one end and 5 at the other. The insulator at the far end was a plastic curtain ring. Worked a lot of stations with that wire. Anyhow, it was fed using a method similar to the one George describes. The biggest rig I had at the time had a 6146, and when the transformer blew, I used a homebrew 6AG7-6L6 rig with oh, I don't know, maybe 15 watts or so output. (For all the junk I had, I was never able to score a decent meter to monitor the plate current.) Obviously I couldn't afford to use up the 15 watts lighting a fluorescent tube, so I just used an NE-2 at the transmitter end of the wire for tuning. Because of the cramped quarters, the rig was on a wooden bookshelf next to the window, with the homebrew breadboard style tuner on top. Once when a friend was over, I was chatting with someone on the radio, and he was looking out the window and leaning on the bookcase. Somewhere during the conversation, he sniffed a couple of times, and said, "Hmm. I think I smell something burn. . ." He turned his head to look at me, and then he saw the white smoke curling upward from his thumb, which had been resting on the tuner. Pretty nasty burn.

Just think of the tales you'll be able to tell the newcomers about the good ole days and the cool things you used to do with your Icom, MFJ tuner, and Gap antenna, when you get to be an OF like me!

Roy,

B, L and E's observations apply only to their test frequencies and local
soil constants. Unfortunately they forgot to measure and record the local
soil constants at their test frequencies.

Their broad conclusions were predictable even if their tests had never been
made.

I am not decrying their efforts. But we should not attempt to apply the
results of their MF measurements to the whole RF spectrum.

It's interesting you should say that. My posting was in response to a generalization that didn't include any allowance for frequency or ground condition at all. Surely we should apply the same cautions to your generalizations as to BL&E's.

You're absolutely correct about the soil conditions. However, it's still difficult to make a decent measurement of soil conductivity and permittivity at radio frequencies, let alone measure it to the depth in which significant currents flow at 3 MHz. There's no reason to believe that a low frequency surface measurement bears any relationship at all to the conditions at 3 MHz and depths of ten or twenty feet. So I think we should forgive them for not making a measurement that would likely prove to be wildly inaccurate anyway.

Today there are tools like NEC-4 that can do a reasonable job of modeling an idealized system at least. As I mentioned, NEC-4 results are reasonably close to BL&E's if you assume ground conditions appropriate for the rural setting where the tests were made. (The pictures also indicate that they were made in the winter, when the soil was likely to be reasonably wet, although there's no way of knowing to what depth except perhaps researching the precipitation data for that period.) The general trends and conclusions BL&E saw are seen also by the program. That makes it possible to extend their results to other frequencies and ground conditions. From NEC-4 analysis, and what you'd expect from the setting, the ground was pretty decent for BL&E's tests. In poorer ground, we would expect the current to decay even more slowly along the radial wires.

Nah. Except for a few really hair-raising times on (or off) the Norton (and Lucas, Prince of Darkness, diabolically springing from the same country as the magnetron), and well, maybe the time the bear took a leak on the side of the cabin. . .then there was the time in New Orleans, but that's pretty murky. . . actually, a lot of it is pretty murky. . .it's all really dull. You wouldn't really want to know.

Or until it gets hit by lightening.
We had a direct hit which removed every bit of tape and coax seal. The stuff
came down looking like a piece of expanded metal.

It even removed the silver plating from the PL-259s on the other coax up
there. (after removing the tape and coax seal as well)

There wasn't one bit of any seal left on the 7/8 Andrews connectors and
they looked like they'd been burnt over most of the surface.

The antenna looked like an exploded cigar up near the timp. It ended about 6
inches sooner than it had before.

If it is in an ordinance it should be defined in db/distance and possibly time periods. If you get a cheap Rat Shack db meter and actually measure the noise at your antenna base I'll bet it is way lower than almost any of the ambient noises in the neighborhood.

What you should do is stand outside your neighbor's house on "a warm night with the windows open" and measure his ambient noises - like when he flushes the toilet or sneezes, etc. - it will be way louder than your rotor brake. That should shut him up... >:)

> experience with the NEC program ?

> Any suggestions or comments are greatly appreciated.

Hi, Robert. Rather than increasing the boom length, consider stacking
two in the horizontal plane. This will narrow the beamwidth. At UHF,
such stacking is fairly trivial.

Once you get past 5 or 6 elements, you are looking at fractions of a
dB improvement for each additional element. Sometimes it is better to
just do a bit of stacking, where you gain approximately 3 dB each time
you double the number of stacked antennas.

Let us say that you stack 4 identical antennas:

Assuming you get the theoretical improvement, then that 20+ dBi gain
necessary suddenly becomes only 14+ dBi for each antenna. Or, if you
stacked 4 of the 17.5 dBi antennas, you get a theoretical gain of
23+ dBi.

All antenna modeling software gives approximations - sometimes good and
sometimes rather marginal. All they do is reduce the "cut and try" that
is necessary to optimize the system. You still have to get out there
take measurements.

That hill could be a real problem. Do you get any signal at all now?
Have you tried moving all over, up and down, with a test antenna.
Sometimes just moving a foot or two can make a large difference in
signal strength.

Source record: 151809

I went and looked at the GAP antennas website at this Super C antenna. Based on the description of the circuit and the design, this appears to be a version of the EH antenna (info on this design can be found by doing a search, like on Google, using "EH antenna" as the criteria). One article that I read describes the antenna as a open plate capacitor built on a pvc tube with phasing coils and a capacitor. There is also another page out there that has on it a description of an EH-style antenna that uses a flat plate and an inverted cone. I see this cone being analogous to the cubical basket on the Super C.

GAP's website says that the antenna "Efficiency approaches 100%" (found on page http://www.gapantenna.com/superc.htm). What is the definition of efficiency here? My dummy load is almost 100% efficient - it's a resistor. Having a 1:1 match does not imply that you are radiating 100% of your energy applied.

I did not find any specifications as to antenna gain related to a reference radiator, either isotropic or dipole. All that is there is "Primarily a vertical = Omni- Directional - Low angle coverage". I would love to see an independent testing lab range test this antenna and see what its capabilities and patterns are.

I suggest reading the pages found by the search and make up your mind. Until I see verified testing, I myself am witholding judgement on this design.

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a0sel6$2n8$1@helle.btinternet.com>
Source record: 151808

The conductivity of copper (for example) is independent of the skin depth in copper. It is a property of the material itself.

The conductivity and permittivity of soil are also properties of the soil itself and independent of the depth to which 3 MHz radio frequency currents penetrate into it.

Conductivity and permittivity can be measured, indeed SHOULD be measured, on small soil samples with dimensions ideally much less than a wavelength at the test frequency and also much less than skin depth in the soil.

Such measurements can be made in a laboratory or on the shack bench with an Autek or MFJ antenna analyser. Problems lie only in the soil container.

That BL&E did not make any measurements of soil characteristics, not even at DC or 60 Hz, indicates a considerable lack of appreciation of the fundamentals of groundwave propagation which had been fully analysed and made available by Sommerfeld and others about 20 years before.

I repeat, I have no wish to decry BL&E's work which was essentially practical and appears to have been instrumental in adoption of the 120-radials standard.

But I cannot rid myself of the thought that if BL&E had become fresh-out of wire after laying 63 radials instead of 118.5 the world would have adopted a 64-radial standard. And everybody would have been just as happy without ever realising the enormous saving which had been made in shallow-buried copper wire.

Hi,
the plastic cup will not last too long up there in the sun and break down.

Try using a pvc pipe cap (.5 to 4" sizes) instead of the cup.
East to drill holes in it and you can paint it if you want to.
find it at any home depot plumbing dept.

73 markII

Just wondering if I need to protect the feedpoint from getting rained
on? Maybe I will build a little cover for it out of a plastic cup
that I could suspend from the rope holding the antenna up.
Any comments?

Roy Lewallen wrote:
"At least one problem is that it (B, L, & E`s work) doesn`t account for the considerable coupling among radials that takes place."

OK. I learn a lot from these exchanges. This may be another gem.

The current in all radials begins in-step at the antenna base on all radials. Under normal conditions it stays in-step at the same distance from the antenna in all radials. The equipotential lines at the surface of the earth around the vertical antenna are circles. I am assuming a single radiator. This means that at any given distance from the antenna, the voltages and phases on all radials are the same. The propagation velocity, whatever it is, is assumed to be the same in all radials.

If there is no potential difference between radials at any given distance from the antenna base, what impetus exists to cause current between radials?

Ed Laport`s idea is that no current between radials should exist and that none should be encouraged. He advises against any interconnection between radials as it might produce "eddy currents" which could only increase loss.

Without current in one radial causing a voltage in another radial, where is the mutual impedance (coupling)?

The total current ideally divides equally among all radials, just as it would coupling or no coupling.

This "coupling" might have as much effect as paralleling two identical transformer secondaries to feed a load in place of one. But, I think the effect is even less because our antenna system load is becoming more dispersed with distance. Thus, there is less potential interaction afar.

Best regards, Richard Harrison, KB5WZI

I want to built a spinning antenna, 600 rpm or more. I was considering a 3 element Yagi-Uda, with the driven element a static mast with director and reflector rotating about. This complicates the drive arrangement. Would using carbon brushes typically found in electric motors on copper rings introduce much noise?

Organization from which I retired used a lot of Kraco brand halfwave vertical sleeve dipole antennas, mast - mounted above 50 ft towers for "local" communications on 42 mhz FM. They gave excellent performance and, built to rugged specs, were also very durable.

Perhaps at your location, both the moisture content and the type of soil
are constant with depth. They certainly aren't at most other locations,
including here. Both vary a great deal, so a measurement of a surface
sample isn't necessarily at all representative of the overall
characteristics seen by the RF currents.

That's most interesting. The folks at the Naval Postgraduate School,
NRaD (Naval Research and Development Center), and others I'm aware of
use some sort of buried transmission line test set. Have you published
your method? If not, would you post it? I know a number of people who
would be very interested in a simpler method that gives reliable and
accurate results -- or even a good approximation.

It's more likely that they realized that a 60 Hz measurement has no real
relationship to the characteristics at RF. The conductivity of soil
typically varies more than 2:1 over the HF range (a characteristic
you've surely verified with your antenna analyzer measurements). The
dissipation factor of water itself, one of the important constituents of
soil, is a great deal different at RF than at 50 or 60 Hz (nearly zero
at 60 Hz, 0.04 at 1 MHz, and 0.005 at 10 MHz, for pure water).

Their paper also includes results for 60, 30, 15, and for some tests, 2
radials. Are you saying that the choice of 120 as a standard rather than
one of the other even better documented results is simply because the
largest number they used was 113 and not because of the results they
presented?

I hope you'll share your soil test method with us, along with some of
the results you've gotten from your measurements.

I was speaking of an off center fed dipole that is fed with ladder-line
with no current balancing circuits at the antenna. Seems it then comes
down to Ohm's law and the feedpoint impedance seen by each side of the
ladder-line.

True. Copper is a homogeneous solid.

>The conductivity and permittivity of soil are also properties of the soil
>itself and independent of the depth to which 3 MHz radio frequency currents
>penetrate into it.

Not true. Soil is a nonhomogeneous aggregate, and its properties vary with location and depth. Topsoil has a large percentage of organic material while subsoils have much less organic material. Subsoils are also much more compacted, and may contain large rock inclusions. The percentage of water in soils of differing compositions and compaction also differs. Soil composition also varies widely from one spot to another, even in the same field or yard. It is nothing like a solid block of copper.

Because of the compaction issue, measurements need to be made in situ unless you can duplicate the compaction in a bench press. Because of the ionic nature of the fluids in soil, measurements made at DC (or near DC) will be wildly different from measurements made at higher frequencies. Etc.

Am I mistaken, or can you make this same argument for two parallel elements fed in phase? It's easy to demonstrate that there's coupling, and corresponding effects on feedpoint impedance, current magnitude, and current distribution, between two parallel elements fed at any relative phase angle, including zero. For something that imitates radials more closely, put up a two sloping vertical wires in your back yard, with the bottoms converging to nearly the same point at the ground. Excite one with a signal, and observe the signal at the feedpoint of the other. If there were no coupling, there would be no signal on the second one.

Hm, in fact, you could use your argument to conclude that there can't be any coupling between windings of a 1:1 transformer. It appears that there's a flaw in the reasoning.

The antenna you describe above is called a "Windom" in my 1957 ARRL Handbook.
The off center fed dipole fed with balanced transmission line version is called
a "Two-wire off-center-feed" in that Handbook.

You can find the definition of antenna efficiency defined in any
textbook dealing with antennas, and it's always exactly the same: The
efficiency of an antenna is that fraction of the applied power which is
radiated. The remainder is converted to heat.

The efficiency of a perfect dummy load is zero, and that of a typical
dummy load much less than one percent. The EH antenna, when constructed
to be much smaller than a half wavelength in size, is nowhere near 100%
efficient, and to my knowledge no reliable published test data exist
that show differently. In fact, if any reliable published test data
exist at all for this antenna, I'd very much appreciate knowing where.

If an independent test lab were to measure an EH or "cross-field"
antenna and verify the results that the inventors claim, their sales
would explode, they would all become filthy rich, and the cost of the
test would be made back many, many times over in a very short period of
time. So you might wonder why they haven't made the modest investment to
have these tests done -- or, if they have been done, to widely publicize
the results. But I don't.

Hi Richard,

I would add a couple of comments to:
>If there is no potential difference between radials at any given
>distance from the antenna base, what impetus exists to cause current
>between radials?

You began with the scenario set to the drive of the system. In that regard you are considering only the conductive side of it. As you point out, without a potential difference, there will be no current flow. However, there are many points for any single point to consider in this comparison of potentials, not just those in the concentric region (consider there is potential difference along the radial itself which is consistent with the current flow, that same point sees its own radial as well as the others). It is only by virtue of symmetry that those other non-concentric points cancel out in the grand scheme.

However this is not to say that the intervening ground between the radials sees these same potentials (well it does, but there's more). The radiation also couples to ground, and at a different current/voltage distribution than that found in the radial; it must, the two are out of time-phase what with the ground's ability to change the velocity factor along the radials, whereas the radiative coupling only arrives at this characteristic after the fact. Again, symmetry here is also a boon.

In so far as cross connections and LaPort's admonition: since in effect it describes a crude approximation of a conductive plane, I see no problems being introduced by these additional connections. Some 20 years ago, PC board designers were coming to terms with ground at high frequencies where busses were exhibiting killer SWR that just devastated CPU timing requirements. The practical solution was the abandonment of point-to-point grounding with advent of power and ground distribution through complete layers in the board (a continuous sheet of conductivity that also aided in signal shielding). This has survived the test of time and the steady progression of upwardly climbing CPU clock speeds (from the HF back then to the SHF of today).

At the onset to this same era of change, I recall the debate of "eddy currents" being made then too, a topic that has not since seen the light of day.

Reg, I tend to agree with Walter Maxwell that the dipole should be at least 3/8WL at the lowest frequency of operation which gives an SWR on the 450 ohm ladder-line of about 20:1. The SWR for a 1/3WL dipole would be about 66:1 which is getting pretty high even for ladder-line.

Without a bit of further investigation, I wouldn't dismiss this thing. It would appear that the point of this device is to increase the area of the ground plane. If it was effective in doing so, an increase in performance is likely.

Ah Punchinello!

Your last comment is the proverbial "left handed complement" which you
typically invest into a "back handed complement." Like Iago, you are
simply playing to your Green Eyed monster.

Indeed, to dwell on what they did NOT do; and to what payoff? Hardly
matters given some 10,000 MEASURED installations proverbially spread
across the vast complexity of grounds that would have revealed these
"speculated" flaws in the Brown, Lewis, and Epstein test paradigm. If
from among these 10,000 opportunities you cannot find a citation that
supports your issues, then I would offer they are only that: YOUR
issues. If, on the other hand, you do have citations to offer, that
would be a refreshing change....

This strain of the Old Wive's march is a frumpy tune enjoyed only by
those who wish to recapture the verisimilitude of the tinny sound of
the Atwater Kent.

Actually I made the 80/40 dipole out of 450 ohm ladder line and
fed it with 50 ohm coax.
I cut the top part for 80 and the bottom part for 40.
There were nulls on these bands. Which I thought was necessary
for an efficient antenna.
I don't have an automatic antenna tuner and hate the idea of
tuning, tuning all the time as I change bands.

But your antenna does sound interesting.

I wonder if an automatic tuner would work with it. It I got one.

Gary, I agree with everything you say.

Different conductivities and permittivities must be expected in soils at different depths. Are they not different soils, the products of different processes ?

But regarding independence of G and K of depth, the depth I referred to was not the depth of the soil below the surface but the depth of penetration of 3 MHz radio waves.

Regards, Reg G4FGQ

You are correct with the the definition of antenna efficiency. I was trying
to
put my tongue-into-hole-in-cheek with the comment about my load resistor
being almost 100% efficient - If the resistors eats all the energy it is
given and
sends none back, then it is almost 100% efficient in these terms. It just
matters
where the point of reference is.

W9INN makes a broad line of wire antennas that would serve this purpose.
One of the more popular ones is the MPD-5-78' or 87' five band dipole.
It offers resonance on each of the 5 bands so no tuner is required. It
is also rated for 1500w pep and there are no trap capacitors to blow
out....

Illustrations, measured data, and contact info is located on the web
site listed below...

I should have mentioned the MPD-5-78' or 87' resonant band coverage is
10-15-20-40-80m

Doesn't the company [Delta Alpha] put out a dipole that works down to 80m
that's less than 100ft? Just a thought. Don't know if you wanted to buy,
build or build if you couldn't buy.

I just did a little analysis.

0.375 lambda dipole, 130 feet of 450-ohm 14AWG feedline, SWR=21, overall loss, Tx to free space, including tuner = 1.2 dB.

0.333 lambda dipole, same feedline, SWR=38, overall loss including tuner = 1.9 dB

Difference = about 1/9th of an S-unit.

Use program DIPOLE2.

From: Leland Cox <lcox107@home.com>
Message-ID: <3C3220E4.A2946DA2@home.com>
Source record: 151745

How does a large number of radials compare to a grid or simply
connecting the ends of the radials together or several circular
connections.

Of course connecting two radials together would not be practical, but
connecting the ends of 120 radials together would be easy.

This is one of the few discussions I have followed, for two reasons! The
discussion has stuck to the subject and very little name calling! From
the number of posts, it seems many have followed along!

You were quite right about 6 meters for the last 5 days. Condx have been terrific from just my mobile station with a 1/4 wave vertical and 100 watts in Virginia USA.

I've been working Europe and the Carribean quite a bit. Even heard a JY9 (Jordan) today on 6 meters but the pileups were too much for my little station.

I'm working on a project of putting a full wave horizontal loop for 6 meters on my truck (vehicle - automobile) while the Solar Cycle is at near peak and F2 DX is terrific.

Thanks for all the replies guys. I appreciate it. I plan to buy a Radio Shack (or similar) mast and build the discone for use on Field Day Events.

Happy New Year

Dan (KA0SDU)
rsmtmn@aol.com

60. A better-built screwdriver antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-01 21:11:40 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <wypY7.128001$BX4.8158983@e3500-atl1.usenetserver.com>
Source record: 151749

About once a month, I will put a blurb on here about my Carolina Cyclone series of screwdriver antennas. I hope I don't annoy anyone by doing so, it's just that I get quite good responses in this manner.

One of the advantages of the Carolina Cyclone is that it is more cost effective while delivering performance equal to or beyond that of the more expensive ones. Thru careful research and. with the assistance of a professional plastics supplier, I have found a material that meets all the requirements of the more expensive competitors in toughness, UV resistance, and power handling. This material is UNMW,or a kind of black Nylon similar or the same as Nyloc used on locking bolts (the little black or white collar near the head). The material turns well for the machinist and further reduces the cost because it produces less waste. Delrin is very high cost, and actually costs FOUR times that of UNMW. Most machinists dread to turn Phenolic because it, too, produces a huge amount of waste, comes off the lathe in long strings of fabric, and causes a huge mess to be cleaned up when finished. It, too, costs almost 4 times that of the Nylon derivative. Back to Delrin. What the fellows that use this hugely expensive stuff don't tell you is that, while Delrin IS very tough, UV resistant, and makes great antenna coils, it is also brittle--meaning that if you prang your coil on a low garage door header, it is more likely to break. We DO make mistakes sometimes. LOL! Now I do not mean to degrade the rival materials because they are good antenna coil forms. But the point I AM making is that there is something out there that will do the very same thing at a more reasonable cost.

And that is where the Carolina Cyclone I & II come in.

Cyclone I is a FULL 2" dia
Wire is #14 wound at 8 TPI
Form is UNMW (black Nylon)
Decoupling fingers are a full 1/4" wide for strength, longevity, and tight contact.
Power handling is 800 watts (warranted)
Hardware is aluminum, brass, and stainless steel to resist corrosion and rust.
Coil cover is 1/8" wall LEXAN for a clear weather protection for many years

(Butyl will crack and discolor in a year or so)
Price is just $240 shipped (less whip) to lower 48 States Includes all ferrules, collets, and parts necessary..

Cyclone II is identical to the one above except it is a FULL 3" dia for the absolutely "persnickety" and avid HF mobile DXer. This is for the fellow that wants Texas Bugcatcher
performance and screwdriver convenience. The one who wants "Q" factors in the 400+ range.
Construction is to the same commercial-grade standards and good looks as the Cyclone I.
For example, most "generic" screwdrivers use a wood insert screwed and glued into the bottom
of a PVC reducer. This has very little in the way of threads, will sometimes strip, or come out of the bottom of the coil altogether. Without revealing too much, I have incorporated a 1" long
turnbuckle nut which has the corresponding length of internal threads. It is secured in such a
way that it is almost impossible to, either pull this assembly out of the coil, or to strip the drive
nut. I have repaired some screwdrivers that "mysteriously" stopped travelling, and the cause was that the brass wood insert pulled completely out because there is not enough material in the
PVC bushing to keep it in there securely. Yet, if disassembly is ever needed, each subassembly can be taken apart, repaired with commonly available hardware, and put back together.
Cyclone II handles a FULL 1500 watts SSB! And costs only $350 Shipped to lower 48 states. Compare those prices to some of the big name screwdriver makers! I guarantee performance that will both please and surprise you, or your money back. For those of you who
have never heard of me, I can say that I have shipped Carolina Cyclones all over the US--many to readers of this newsgroup. In 6 years of building, I have had exactly ONE to return for a
mechanical failure, and I swapped it out immediately. You will find no negative remarks on the
internet about trading with me--I do what I say or I make it right. If I didn't, I would be out of
business in short order. But I want to STAY in the antenna business because this is one of the
aspects of ham radio that I love working with.

Earilier, I said that I have a goal. My production is small--anywhere from 2-3 per month except during hamfest season. I don't try for huge numbers because I acquire the parts, I
assemble, I test, and I ship! When you get an antenna from me, it is, indeed, from me! I have
no employees. I work for myself. I need to make that goal of 3-4 antennas during January.
If you are in the market for an HF mobile antenna, please help me make that goal AND receive
an excellent product in return!

Thank you for reading, and thanks to all of you who have purchased the
Carolina Cyclone
in the past.

Happy New Year, and the best of 73 to all,

Jerry
K4KWH

61. Where and what kind of antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-01 21:14:46 UTC
From: Charles Gallo <Charlie@thegallos.com>
Message-ID: <uf943u06d33hbg789gv49hhufqu040usdl@4ax.com>
Source record: 151750

Hi Gang,

I'm very new to this hobby, and I've got a question or two. It looks like it's probably time to put up my first antenna. The intended use is 2m/440Mhz FM repeater use. The repeaters that I really want to work, I can work right now with my HT and its stock rubber duckie. I'd like to put up a nice omni antenna

That said, I have 2 options on WHERE to mount my Antenna

option 1) On old TV mast over the main roof - this will require a 75 foot coax run, and a lot of work - it clears the roof by about 6 feet

option 2) on the chimney of the extension - this is about 10 feet lower, and is maybe 5 feet below the roof line - the advantage is that the coax run is about 25 feet, and easier to do

Hello All,

I'm looking for ferrite- mix Stackpole 24B

I'm looking for this material or its equivalent in rod form, 12" long by
0.625" diameter

If you can help please reply off-list.

Thank you,
Erik
sumpcaver@att.net

Superb. I'm a TV/FM=DX monitor in Puerto Rico and am not catching any
signs of the openings. Can you suggest any times that you see these
openings?

No, fergit it. Even the best my local power company can do with bare wire+treebranch and 11,600 volts is the occasional arcing enough to wipe out any BCB reception. 500 watts or so of RF on an insulated wire tangled in tree limbs will rarely be a problem.
That being said, watch out for the sap-rising season and a few anecdotes of where it really did occur.
;-)

You can glue smaller rods together to reach 12" ...but, I don't know any specifics to that particular mix. If you would elaborate on the project at hand you may find some good alternatives.

There is not much spare wire in a 1" dia 7 turn coil. I suppose I could calculate the inductance, but not on New Year's Day.

This is the way the cable company installed it. I watched it being done.

The coax feed comes through the wall and to a splitter. A single conductor insulated ground wire - about 10 or 12 AWG - is connected directly from the splitter to the closest cold water pipe. Immediately prior to the water pipe connection he wound a 7 turn 1 inch diameter coil, he used a tool to wind it to the desired diameter. At the time I did not think to question him since I was waiting to go out.

Since then the power line on our street has been completely replaced and I have noticed that all connections to the pole ground wires have a similar coil/inductor immediately prior to the connection to the pole ground wire.

Incidentally, since the new line was put in a considerable section was destroyed during the ice storm of '98. It was rebuilt by a crew from a different area - I forget if they were from Canada or the U.S., but the coils in the ground wires have been replaced so it does not appear to be a local thing?

As an added item which might or might not be significant; the telephone and cable TV distribution on the poles is all fibre-optic; and labelled as such at each and every pole.

It just struck me as odd to put an inductor in a ground wire which might be subject to a lightning surge.

Dave

Best Wishes to the group for 2002.

Tony,
Carbon brushes would cause problems that you shouldn't have
to worry about if the driven element is stationary. Although,
600 rpm is going to be the 'kicker' at anything but UHF. I'm
wondering what your going to use the antenna for?

hey charlie
what i would do is use the chimney and just put a longer mast on the antenna
radio shack sells a chimney mount its a couple of steel straps and stuff to
secure the mast to the chimney and then put 10-15 feet of mast that way the
antenna clears the roof
remember in VHF/UHF the higher the antenna the further you can talk
also remember to use a low loss coax something like LMR400 or 9913F cause at 440
mhz you will be looking at 3-6db of loss in a 50 foot run or so
good luck and welcome to the hobby

Hmmm, height vs loss. In VHF, the first guess always is to go with
height. But you say you can work 'em from a HT already so my guess is
that you aren't pushing that limit with a 10' difference. I'd say take
the easy route. If by some fluke the roofline interferes, you have the
other option. The difference in coax loss won't be a determinimg
factor. An outdoor antenna inside a trampled-on aluminum garbage bag is
better than a 3" HT whip.
As for the Berkley stuff, you are pretty much alone in that perspective
of reality. Harmless, and you'll grow out of it :-)

You need to watch that ad a little more closely. The range enhancing device is being sold as the main product. The other product meant to prevent the radiation is thrown into the deal. That device fits over the speaker and is, of course, snake oil.

Hello All,

The ferrite rod in the previous post is needed for a LF project. I believe that the mix has a u ~2000.

I mistakenly stated the dimensions as 12" long by 0.625" dia. The diameter really needs to be 0.75".

I've spent many hours searching the Web for this rod and I've turned up very few leads. Amidon seems like they may be able to supply this, however I have to wait for their staff to return from the holiday and hopefully they reply.

I would think the "snake oil" product, the one that attaches over the
earpiece,
could be marketed to improve signals since it is closer to the antenna, and
would help
improve the coupling to the head so it could serve as a counterpoise... Far
fetched.

The "range improving" product I've seen is a mylar strip that mounts on the
back of the
battery. I could place a 19" wire under my trunk and claim "improved"
two-meter
mobile range.

Can anyone show a link to where consumer or other independant group has
shown where these
things can provide any benefit other than to the seller??

Aw, heck....I see these things on ebay for 75 cents. Is this any
different than a kid that wanted ten whole cents for a cup of lemonade
30-40 years ago? Maybe the topic of discussion should encompass the
precedents that lead to capitalism rather than boo-haha because the
product is overpriced crap that couldn't find space in the local "dollar
store".
Go buy a bag of lemons and make your own lemonade and figure out a way
to hawk it on the internet at such prices so you can quit your day job.
This is why the South Coast of France isn't overun with big-spending
techno-nurds..

You will see a distinct directional effect with the typical loopstick.
Normally its broadside to a ferrite loop for max signal, and yes, you
can use that feature to separate or ID certain stations.
Mountains can be a big problem on short distance AM reception...I detect
that you are in Taiwan?? I have no idea of your conditions but its not
uncommon outside the USA for stations to have low-power repeaters
on-frequency which will screw up ideas of where the actual transmitter
is located.

Okay....I'll agree that its snake oil. My local lottery offers 'riches'
based on the same concept but they charge more than these 'cellular
enhancers' cost.
My locale, PR, has the highest rate of telephone lines vs. population
and has even a higher rate of cellphones per capita of anywhere else in
the universe. A population of scarcely 4 million has 2 million
cellphones. If there is a 75 cent trick to be had, we know it locally

but if you fly VFR you'll be dodging the tower blights on the
landscape. Cell-saturation.

Roy,

Regarding independence of conductance and permittivity versus depth, the depth I referred to was not the depth of the soil below the surface but the depth of penetration of 3 MHz radio waves.

> The folks at the Naval Postgraduate School, NRaD
> (Naval Research and Development Center), and
> others I'm aware of use some sort of buried
> transmission line test set.

Trust the Military to squander a fortune of tax-payer's money on men, time and equipment when what is needed is a borrowed 259B and a pocket calculator.

> Have you published your method? If not,
> would you post it? I know a number of people
> who would be very interested in a simpler method
> that gives reliable and accurate results --
> or even a good approximation.

I've no wish to start a stampede to the US Patents Office. I had no idea that such knowledge was at a premium stateside. But if anybody would like to buy the idea I'm open for offers. Roy, I'm sure you could devise a method which could be used in the average radio shack if you really tried.

Actually it's not worth all the fuss you make of it. If any measurements are needed at all, an accuracy of plus or minus 30 percent is quite good enough for radio prediction purposes. Eznec will demonstrate that. With experience and freedom from any delusions of accuracy, a visual examination of the ground is sufficient.

> It's more likely that they realized that a 60 Hz measurement has no real
> relationship to the characteristics at RF.

Roy, you'll have to face up to the fact that it didn't occur to any of them that conductivity measurements at any frequency were of any consequence. It would have taken only ten minutes to make measurements at DC, 60 Hz or ELF. Other people had been making such measurements for years. Soil conductivity was of fundamental importance in understanding what goes on.

> Their paper also includes results for 60, 30, 15, and
> for some tests, 2 radials. Are you saying .... ?

All I'm saying (before it became a Federal case) it's a great pity they forgot to make any soil conductivity measurements. If the site still exists has anyone visited recently to fill in the gap in our knowledge.

I prefer soil "resistivity" to "conductivity". It's in line with
everybody's way of thinking about volts, amps and ohms. The sizes of
measurement units, ohm.metres, also have practical values. An Ohm.metre is
very simply the resistance between opposite faces of a 1-metre cube of the
material. Most soils are in the range 20 to 50,000 ohm-metres.

Regards, Reg

Source record: 151674

Hi Richard,
the gap super C antenna can do the promised job .
I did early experiments on it looking at the patent.
He can be really quite efficient.
BUT is a traditional resonant antenna , on the site they describe very well
the working principle.
The only doubt I have is they declare perfect performances over different
frequencies....
Is not possible, that antenna can be efficient only on ONE F. On the others
is a compromise.
I tested that.

About eh antenna, please don't be confused.
The eh antenna works on a totally new application.
I mean the physic laws are well defined and nobody can change them.
The eh antenna works on a new NOT resonant way.

I agree with Roy and other skeptics guys....but...
at the moment we decided to reveal ALL the instructions to have one of it
built just to show how great can be.
In the future we will provide any scentific ,indipendent , measures.
I know can be a criticable strategy, but is the our strategy.

Ted Hart will provide , very soon, with a perfect test on a AM version
following the severe FCC rules.
In the counter part here, in Italy , we launched the ham version .
Again, we sent, up today, about 500 documents on the eh practical
building....
We are collecting a lot of complete success stories on eh , perfectely built
and compared on a professional ways.
You can believe it or not, but I can produce all the ham calls having a
complete success with 1% wav. long ehs producing the SAME efficiency
respect to full size dipoles.

again we think the better way to decide IF the eh antenna works or not, if
simply build one of it.
It costs almost nothing, is fast to do AND I am here to drive anybody wants
have a test on it.
What is the risk?
YOU could waste some time having fun experimenting with antennas, in other
words I offer you the possibility to do what any ham should do...experiment
in the perfect ham spirit.

I am here ,just let me know if you want play with it.
sincerly , stefano IK5IIR

Roy Lewallen wrote:
"Am I mistaken, or can you make the same argument for two parallel elements fed in phase?"

How about wire of a larger size. It`s about the same thing.

Consider adjacent radials. These are comparable to the sides of a bridge circuit with excitation applied between the near end and the far end of the of the pair of radials.

Excitation of the radials comes from displacement current in the space between the vertical antenna and the radials.

Take the same distance along both radials to connect a bridge detector between the radials.
Makes no difference what percentage of the applied voltage appears at the detector points. It will be the same voltage on either radial wire if symmetry prevails as it should. There will be no potential difference to motivate a bridge detector. As long as balance is preserved, the radials don`t affect each other.

As an example consider a transformer with a pair of identical secondary windings, each with the same configuration of multiple taps. Assuming ample transformer capability and equality between the two windings, it makes no difference if all the corresponding taps are interconnected or left unconnected when the secondaries feed a load.

Ed Laport was concerned about assymetry in a ground system producing eddy currents, should radials be interconnected at points remote from the antenna base. With perfect symmetry there is nothing to worry about. Ed worried because perfection is elusive.

Best regards, Richard Harrison, KB5WZI

Reg, EZNEC gives SWR = 66:1 for a 0.33WL dipole on 75m fed with
450 ohm ladder-line. Feedpoint impedance is 21-j645. How much
loss it there when the SWR = 66:1?

You don't want a spinning yagi for a doppler. This will add AM modulation
you don't want.
However, you can do DF this way, with a sin/cos pot, and storage scope or
microcontroller.
You don't need or want to spin fast though. 1-2 scans/second will work fine.

A November 1996 price list from Amidon I have lists a .75" diameter X 12.00"
long rod of
#33 material (mu = 850) for $100.00. I don't know if they still sell this, but
it seems a bit on
the expensive side to me.

Dick Carrol wrote:
"Organization from which I retired used a lot of Kraco brand halfwave vertical sleeve antennas, mast-mounted above 50 ft towers for "local" communications on 42 mhz FM."

Organization I retired from did not use such coaxial antennas on fixed stations but used many on boats and ships because they had no radials to poke out an eye. Our radios were mostly at 33 MHz and in the 150 MHz band, but we had many other radios in many other bands. FM was used in most bands, but we had many aircraft and other applications.

We used only folded radiating elements on our VHF FM fixed stations. If we were forced to use a non-folded element we shunted it with a 1/4-wave short-circuited stub across the drive point and made a good coax ground to the tower at that point. Through the decades this proved the only way to avoid lightning damage. We had hundreds of installations, some on towers up to 400 feet. This worked as an essential lightning protection element.

Andrew supplied our unipoles on whatever frequencies we operated on, if we could get them. We never quit trying other antennas, but never bought any significant quantity of base station antennas made by others with the exception of 2 GHz grid dishes made by Anixter-Mark.

Our coaxial antennas were usually supplied by Motorola and manufactured by Mark Products or whomever Motorola chose at the moment.

Cecil asked if the sleeve were insulated from the support mast. Our coaxial antenna skirts weren`t touched by any conductor anywhere but at the dipole drivepoint. The coax was routed to the feedpoint via a pipe extending from inside the skirt to well outside the skirt. This pipe was also used for mounting the antenna to another pipe or some other support. We grounded the mounting pipe.

Our automobile and aircraft antennas were stainless steel whips, usually of the 1/4-wave variety.

For our aircraft beacons we usually installed inverted L`s with multi-wire canopies.

For our jungle SSB radios, we used 1/2-wave dipoles as high as we could get them up.

For our point to point log-distance HF we used a rhombic, etc.

Best regards, Richard Harrison, KB5WZI

Well I have verified that the antenna booster does in fact work at least on the Motorola Startac phones. From the looks of it, it appears to be a resonant passive reflector which would reflect RF below the antenna back up at some angle. The instructions warn about being sure to point the top part upwards to the antenna. They are available at OfficeMax here and I'll pick one up for my xyl's phone which has rather poor coverage and post a report.

Reg,

You keep mentioning how easy and fast it is to make these
measurements. Well, sir why don't you just explain it to those of us
less fortunate than to have you vast knowledge just how to do it?

Cecil, so what ? The addition loss in dB on the line over the matched loss
is not proprtional to SWR. Your reasoning is at fault.

Use program DIPOLE2 for correct comparison between the two dipoles. Takes
only two or three minutes and 99% of that is thinking about it.

If you'd like to have a little fun, learn something about antennas and get on the air for CHEAP, you might consider building a couple Eggbeater IIs as seen at http/://members.aol.com/k5oe - These antennas are great for working satellites on 2m and 70cm and also excellent general purpose antennas for local use.

Of course 2 meter dipoles encased in 1/2 in PVC pipe are cheap too...

I worked KP4 Sunday at about 1500Z from my mobile and 100 watts with a 1/4 wave vertical.

Europe has been coming in from 1300Z at the earliest until 1800Z or so at the latest. The times vary somewhat depending on condx each day.

I've heard some Carribean stations working Europe so just be on the lookout.

106. Smaller versions of screwdrivers??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-02 01:41:27 UTC
From: Max <ve3tmt@rac.ca>
Message-ID: <pytY7.6387$A67.1724873@news20.bellglobal.com>
Source record: 151694

A couple of years ago I was using a BB3 screwdriver mounted on the trailer hitch of my '99 Intrepid. Although it worked not bad, honestly I thought the antenna was just too big for the car. On a F350 or tractor trailer they might look ok, but it looked out of place on the back of the car. Is there a smaller version available, say to cover 40-10m? I don't do too much on 75 anyway, but I guess I would if I had the antenna right? Just curious if anyone makes or can make a smaller version, meaning not as tall or as big a diameter to cover 40 and up?

Thanks,

Max ve3tmt@rac.ca

Reg wrote:
"Hi Richard, so how would you determine soil conductivity?"

I`m one of the Richards, so here is how I would determine soil loss without going into great detail.

Field strength measurements have been made for at least a century. I haven`t been doing it quite that long, but I`ve done some on more than one continent. The FCC has published curves of signal strength versus distance from a transmitter with curves for differing soil conductivities. These are called "Ground Wave Propagation Curves" and are a part of the FCC Rules.

Across a stretch of earth of interest, I would make a field strength measurement as close to the transmitter as I could get, but no closer than 0.1 mile away. Then I would make a second measurement similar to the first as far away as I could but no farther than 20 miles away. These distances are for convenience in using the FCC charts. These distances can be changed to conform with the limits of the area of interest.

All that is left to do is to see which FCC curve best fits the data. These curves are clearly labeled as to the conductivity represented by each curve.

Best regards, Richard Harrison, KB5WZI

I had an HT-18 for several years and really like it. It got out on 80 and 40 real well. I fed it with hard line and put the power to it...but.... when I got the loading coil for 160 I found that I could NOT use it on both 80 AND 160 (without retuning the coil). If I tuned the coil for 160, I couldn't get a low swr on 80 and vice-versa.

==========

Yes the method works. Gives you the average conductivity over the groundwave path. But you don't need to know what it is.

Having obtained a number from the chart you can now go back to the same number on the same chart and predict the groundwave field stengths you have just measured at various distances for a given transmitter power.
Fascinating ! With a little imagination you don't even need the chart.

Actually those curves are incorrect. They all apply to a soil permittivity of 15. Real permittivities vary from 3 to 80.

If my memory serves me correct the curves are useless at HF because they stop at 1.7 MHz.

Best of luck and a peaceful 2002.

Reg.

> Cecil, so what ? The addition loss in dB on the line over the matched loss
> is not proprtional to SWR. Your reasoning is at fault.

Maybe not proportional but certainly correlated. The ARRL Antenna Book
has the following equation:

Total loss = 10 log((a^2-|Rho^2|)/a(1-|Rho|)^2)

where 'a' is the matched line loss and Rho = (SWR-1)/(SWR+1)

Assuming a=.075 dB per 100 ft on 75m, I get very high losses since
the denominator a(1-|Rho|)^2 equals 0.0000675

Are you using the above equation in your software?

Question to all: If Rho^2 is greater than a^2 in the above equation,
we are asked to take the log of a negative number. I'm wondering
if there is an error in the equation.

For (a = 0.075 dB per 100 ft) and (Rho = 0.97) we get
10 log (-13843)

It doesn't make any sense to write |Rho^2| since Rho^2 is always
positive anyway. Should the equation be:

Total loss = 10 log((|a^2 - Rho^2|)/a(1-|Rho|)^2))

In which case the total loss would be 41.4 dB?

>

Doesn't really answer anything at all does it? ;-)

That was toooo easy.

For the others who have higher technical expectations, I would offer
the answer is available to anyone with a modeler. Simply put,
modelers have far more accuracy than your kitchen table approach and
any measured deviation from the theoretical (courtesy of the modeler)
must of necessity represent the variables that we are discussing. If
EZNEC tells me a particular configuration exhibits 37 Ohms resistive
(we are talking a simple vertical here), and I measure something
different, it is in all likelihood a difference that I brought to the
mix - not a fault of the software that has been refined through
thousands of measured observations - away from the kitchen table.

The last time I pointed this simple remedy out to our glorious Herr
Doktor's ground warmer, he sputtered on about special mathematics that
was not included in NEC and the special qualities of Fractals that
rendered common sense passï¿½. Yeah, sure. Perhaps I was off by 10% as
a function of what he said that was reasonably faithful to the
prostituted logic; but the face full of spit from his sputtering would
have suggested I was off by 1000%.

Don't tell me it's raining.

I don't even have to drag a container of dirt indoors to make an
assessment of its contribution to loss, and I can even measure it as a
function of frequency, environmental variables, and the like, in situ.
The single greatest contributor to error is adding your own problems
and improvising tests that are elaborate beyond necessity.

Your methods are simply too filled with the mystique of fossilized academia, leaning on vague and ancient references - common sense solutions are available; the work has already been done; the tools are robust and available.

There does seem to be an error in the equation. The denominator above apparently should be a(1-|Rho|^2)

This is equation (9) on page 19.6 of "The ARRL Handbook 2000".

My apologies to Reg and the group. The total loss on a T-line with a matched line loss of 0.075 dB and an SWR of 66:1 appears to be about 1.9 dB which may or may not be important. My main objection to that high SWR is that it can be transformed by the T-line to 20k ohms at the transmitter end, a value hard to match with an antenna tuner.

>post. Nothing to it.

Well ralph buddy like i said in my post i already figure that out!
That's the simple way out but not the most efficient. As i have to
unplug/plug every 2/3 times per week the connectors are getting used!
And in some months i might have to change them.

Let me tell you though that i have devised all on my own an umbrella
lightning protection for my antennas and it's undergoing tests right
now!

And also it's not only when their are lightings that equipments get
damaged but when there are heavy clouds (thus big static buildup) and
with that protection nothing can damage my antennas and equipments :))
If the tests are 100% positive i will post the details for everyone to
check it out :)

Ralph: I do not waste time posting things! I just wanted to know if
there were professionals who have better ideas than mine. But it seems
some people just auto proclaim themselves 'professionals'! Nothing
personal.

Cheers.

Be careful.
Years back, when I had an open line with standing waves running through the garden, hitting the key started a little fire, when releasing the key it calmed down. The fire could followed the (slow) morse ritme. (output 1KW+)
Wire insulation can make the effect even worse.
With 600 watss output voltages over 1KV rf can be at the end of your antenna.

That's not the only disadvantage. :-) 12 dB down from a good bugcatcher
on 75m sounds like another disadvantage to me. It works pretty well
on 20m-10m though.

Reg wrote:
"Actually those curves are incorrect. They all apply to a soil
permittivity of 15. Real permittivities vary from 3 to 80."

That is a valid criticism, on its face.

Permittivity is measured in Farads per meter.

The earth as a propagation medium for radio waves appears as a
capacitor and resistor in parallel. At very low frequencies,
permittiivity is inconsequential. In the upper HF range, soil resistance
is inconsequential because it is so well bypassed by permittivity.

The fact that the FCC`s curves have been used a million times, the U.S.
must have 10 000 licensed AM broadcast stations, and that measurements
are repeatable while conforming fairly well to the FCC`s curves, attests
to their utility.

In trying to extrapolate the curves it should be noted that at several
times 1.7 MHz the curves are irrelevant due to permittivity which
becomes the medium of propagation.

The purpose is direction finding. The advantage over a "Doppler" is 7
dB gain, no switching noise and AM vs phase detection. Basically I
want to have Yagi performance with the hands off and summation of a
"Doppler". A grey code wheel will address the switched capacitor
filter and display. The antenna will have to be dynamically balanced
for the 2 meter band. It should create quite a whir, simular to an
engine cooling fan.

Roy Lewallen wrote:
"Am I mistaken, or can you make the same argument for two parallel elements fed in phase? It`s easy to demonstrate there is coupling,---."

Yes, if one wire is placed close to a second, the field produced by current in one wire will induce voltage in the wire nearby.

If one amp flowing in the first wire induces one volt in the second wire, the mutual inductance is one henry.

Is this mutual inductance relevant to ground radials? I think not.

The current flowing into the radials totals the current into the vertical radiator.. Ideally, in a non-directional antenna, current is equally divided among the radials.

If uncoupled wires are in parallel, their inductive opposition to current is reduced in the same way as parallel resistive opposition to current is reduced. With mutual inductance between the wires in parallel, induced voltage adds to or subtracts from the applied voltage.

Roy suggested I might use my argument to conclude there can`t be any coupling between windings of a 1 : 1 transformer.

There are two ways to connect identical transformer windings, phase aiding and in phase opposition. Assuming perfection, connected one way the sum of the transformer winding voltages is twice the voltage of either winding. Connected the other way the sum of the transformer winding voltages is zero.

If these same transformer windings were used as inductors, connected one way they would total 4X the inductance of a single winding. Connected the other way they would have zero inductance.

So what? We really don`t need to wory about mutual inductance of radials. Ground radials are not resonant as Reg has often stated. We are merely trying to launch and capture radio waves with an antenna of half the height required of a dipole. We can tune out reactance in the radials, whatever it is, to get the maximum power to the antenna system. The function of the ground radials is to get a low-loss ground connection.

Placement of the radials should avoid the antenna system`s displacement current having to flow through the soil. That`s it!

Best regards, Richard Harrison, KB5WZI

Kind of like asking what the best car is... :-)

But for your general coverage HF receiver, you could string a piece of random wire across your floor. Or string it outdoors, as long as you can make it, and as high as you can get it.

There are any number of amplified antennas that will work indoors or out. The Dymek DA100D works very nicely for me. For outdoors pre-made antennas, I've also had good luck with the Alpha Delta DX-SWL 60' sloper.

Once you get your receiver, it will probably have pretty good instructions for antennas in the operating manual, and possibly even include a simple antenna of some sort, a piece of wire or whatever.

Good luck!

(There are books on this subject -- try Universal Radio)

(Also, try Radio Shack. They have antenna kits for swl listening that include wire, insulators, everything you need.)

Ah Punchinello!

The usual Old Wives fairy tale. Useless?

Knowing the geology (usually available in the form of a "soil map"
from the local commission) and the typical permittivity for the region
from the source offered by Richard, correlations made against those
constituents that MAY vary (and that is hardly to be taken for
granted) can be projected to HF. This variation is more in part to
the water content in the loam than in any exotic electrical properties
(di-electric loss principally) of the various granitic, basaltic, or
anyic continental substructures (gad) you can summon up.

This is the typical abandonment of thinking simply because the "exact"
answer is not available - the sort of argument that allowed fractals
to come to light.

As Richard may agree and expound upon, our common resource found in
one Arnold Bailey offers some interesting data in regard to this
"useless data" (sic).

From his TV and Other Receiving Antennas," page 163 is offered a fine
graph plotting the Intrinsic Impedance of various earths from 100 KHz
to 10 GHz. As this printing is from 1950, the subject was hardly
veiled in the arcana of personal experience and is far more scholarly
than the platitudes of abandonment quoted above.

I shall recap what is encompassed in that fine graph:
Air/Vacuum 377 Ohms over the entire frequency range;
Dry Soil 120 Ohms @100 KHz
Dry Soil 170 Ohms @1.7 MHZ through 10 GHz;
Wet Soil 14 Ohms @100 KHz
Wet Soil 65 Ohms @10 MHz through 10 GHz;
Lake 30 Ohms @100 KHz
Lake 42 Ohms @500 KHz through 10 GHz;
Ocean <1 Ohm @100 KHz
Ocean 14 Ohms @10 MHz

Ocean 72 Ohms @10 GHz

Most of continental America falls into the Dry Soil characteristic with the heartland as Wet Soil. Hard to miss the correlation to the drainage of the Mississippi. The FCC Data offers higher precision, but you are not going to move to the next county and find a vastly better situation, unless it is waterfront property.

If there is any wild card in this data, it is clearly with sea water - not land. For Dry Soil, the FCC 1.7 MHz Data is already calibrated through 10 GHz. For those so unfortunate to live in Wet Soil conditions, you will have to apply a sliding scale (god only knows how hard that is to do without unzipped software).

Hi Richard,

This uncharacteristically off the mark for you.

Given that radials are not harmonic due to being swamped by loss (no
Q) AND due to the fact that they are quite close (initially at the
origin, if not in fact as a portion of wavelength); it is the symmetry
that in some large part maintains the balance of individual currents
THROUGH mutual inductance.

I wrote:
"Is mutual inductance relevant to ground radials? I think not."

Another way to explain may be that currents in a balanced system will still be balanced if equal deposits and withdrawals are made in each radial. A balanced system will remain balanced because anything given away by coupling to other radials will be received in the same proportion from the other radials in the system.

Not to start a new discussion, but it is something like similar objects in proximity and all at the same temperature, They will be radiating and receiving heat at the same rates if they are arranged symmetrically.

145. Newbie Question on VHF half wave dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-02 18:00:01 UTC
From: sander@icon.co.za
Message-ID: <3c3346e7.10982515@news.saix.co.za>
Source record: 151632

This is probably a really basic question, but here goes...

I want to build a half wave dipole antenna for VHF in the marine range, 156.05MHz to 162.025MHz, in particular 156.80MHz.

I would like to build the two legs using alum. rod (Which I happen to have) in a plastic tube. The question is about the join between the two rods. Obviously I need to isolate the two, but is the distance between them important? Also the length of the two legs are 17.5" ea. Do I measure that from the centre of the isolation, or the actual length? In other words, will the total length be 17.5" x 2, or (17.5" x 2) + length of isolator?

Lastly, are there any problems doing it the way I intend?

Thanks
Sander

> I'd never run more than 500 or 600 Watts.
> If the insulated wire was touching a branch or something.

Shouldn't have any problems with insulated wire, even up to 1500w.
I've "toasted" a few tree branches at the ends "hi-voltage point" on
the antenna where "bare" wire touched green tree branches. But they
need to be somewhat green, and have moisture in them to be able to
conduct. I've never had any problem with insulated wire. Even at the
far ends where the voltage is very high. With a KW, it can be in the
7000-8000 volt range at the ends. About a 1/10th of that for 100w
rigs. Only with bare wire against moist tree branches have I ever seen
this happen, and even then no fire, just a browning of the branches
like someone stuck a bic lighter under them trying to light them and
was unsuccessful. I've never seen a fire. It's possible of course, but
for the branch to be dry enough to burn, it won't be a very good
conductor to ground to start the problem in the first place. All my
wire antennas are thrown though trees. Never have had a problem with
insulated wire. And only very rarely with bare wire, at the ends only,
with a KW plus and damp branches. And even then I didn't notice it
from the shack. My amp didn't flinch. I only noticed it later when I
went out to adjust an antenna leg and saw the fried green branches. I
switched to insulated wire, and have never seen it since. MK

> I haven't...

Not only have I heard of it, I've seen the aftermath of a fire started in a pine tree in contact with an amateur antenna installation.

My guess is that arcing between a high impedance point on the antenna and the tree formed a carbon track over many weeks, or months, of operating at QRO power levels. The cavity became progressively more insulated thermally as it burrowed deeper into the tree. Eventually combustion was self sustaining....

Fortunately the fire was spotted before significant property damage occurred.

Yes, tight coupling insures that what happens in one part of a ground sysem strongly affects the rest of the system. I reacted rather than logically explaining. I hope I`ve learned in the process. Sorry my posting may have been unintelligible.

The importance of the radial system is largely replacing 1/2 of a vertical dipole. The radial system`s function is not providing coupling between radials, though that results.

Sander,
The total length would be (17.5" x 2) + insulator. Keep the
length of the insulator fairly short, 1/2" to 1" between
elements(?)
and you should do fine. You may have to adjust the length of
each
element to get the dipole tuned, but it should work pretty well
just as you described it.

There have been several comments here during the last few months concerning the difficulty of measuring the actual earth ground resistance at RF in the "real-world" situation. From this, I assume that RF engineers have no simple way to determine the RF ground characteristics of interest to the field antenna engineer.

It is likely that we could deduce ground characteristics at a specific frequency by making a series of measurements on a simple antenna as it is brought nearer and nearer to the ground and then reducing the measurement data with an appropriate algorithm to solve for the desired answer.

My scientific intuition tells me that when we measure the properties of an antenna in a given environment, we are actually measuring TWO things - the properties of the antenna AND (indirectly) the properties of the environment. If this is true, then when we make a series of measurements in a series of environments, we should be able to infer the differences in those environments by the differences we observe in the measurement data. All we need is the appropriate way to tease the desired result from the data - i.e., the appropriate rearrangement of the fundamental equations.

As a very simple example of this basic idea, we indirectly measure the dielectric constant of a _nearby_ material every time we take a grid-dip meter or antenna analyzer to a length of coax to determine its velocity factor. We are comparing the resonant frequency of the length of wire inside the coax in two different environments, with the dielectric the only environment variable (and with the "other" environment, the free-space one, calculated, rather than measured). It is all done by re-arranging the basic equations in a way that solves for the parameter we are trying to find.

Thought Experiment:

Take a small loop antenna designed for the frequency of interest and make measurements when that loop is (a) in free space vacuum, (b) in atmosphere at a large distance from the ground to be tested, (c) at progressively closer specific distances to the ground, parallel to it, (d) on the ground. The measurements should include parameters known to be dependent on the ground characteristics of interest.

With the appropriate fundamental equations re-arranged to solve for the desired parameter, we should be able to determine whatever ground characteristics are of interest at the measurement frequency, even perhaps including its distance below the physical surface.

(Anyone developing the algorithm please email me full instructions and a copy of the computer program ;-)

Having been there, done that, I can tell you that spinning an antenna at this sort of speed is going to be VERY problematic. Your antenna elements will need to be redesigned to withstand the wind forces and centripital forces. Very non-trivial, and we haven't started moving yet. Did I mention low-hanging trees?

When I did this, we scanned at most 2x/sec, with a 5 element yagi, using a sin-cos pot to feed a storage scope. The pattern was easy to interpret, and the rig doubled as a mini antenna range. The antenna could be stopped in less than a second and easily positioned to best negotiate any arboreal hazards.

I'm not sure what the switched cap filter is doing for you here. You should maybe look at sampling the AGC with an ADC, and doing the averaging in ram. Much less hardware. You could do all this in a mid-range AVR.

The display could be a graphic LCD, or a more practical approach might be a GameBoy or Palm Pilot device.

This also goes by the term "Substitution" in the parlence of
Metrology; that is, you swap in a known for an unknown and observe the
differences.

My approach would be to accept the results of modeling as the "known,"
make measurements of the results of its implementation, "the unknown."
The differences are going to be far more attributable to the local
variables than the modeler.

Seems far more accurate than reading the dielectric constant of mud in
the kitchen sink.

>(d) on the ground. The measurements should include parameters known to
>be dependent on the ground characteristics of interest.

My point (being picky here) was that you can skip steps a and b above
by substituting a modeler, especially for such a conservative design.

159. Re: Discone HF Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-02 21:33:31 UTC
From: Karl Beckman <Karl.Beckman@Motorola.com>
Message-ID: <a0vub0$d90$1@newshost.mot.com>
Source record: 151648

There was a later work with "NVIS" in the title (published within the last four years) which involved using a Radio Shack 40 ft push-up TV mast and four guy wires/elements, with an autotuner at the base. The 50 ft guywires were broken with egg insulators at the halfway point, from which the elements return to just above the bottom of the mast.

I envision something like a "hula hoop" at the bottom of the wires to keep them from shorting to the steel mast, which was directly earthed with four buried radials running out to the guy anchors. I am still in the mental fabrication phase, having only driven some wood stakes to mark where the base and anchors would land in the flower beds.

It sounds as you are referring to a small version of the NORD which has
been around for decades. Used by the Navy regularly. See Capt. Paul
Lee's excellent vertical handbook for more details. This wasn't a
design for NVIS applications - they sought broadband abilities. A couple
of these have turned up surplus and in the hands of amateurs.

Been there done that also, six elements broadside interfaced through
the joystick port. I want to spin it faster with only a director and
reflector. Trees are trees at 40 mph, no matter if the antenna is
spinning or not.

The total length should be 17.5 x 2. The length of the insulator does not factor into the desired length of the dipole, provided you don't make the insulator absurdly long.

A 35-inch dipole will be resonant at about 159 to 160 MHz, depending on how fat your element is. If you have a 1/2-inch-long insulator at the center, the overall length of the dipole still needs to be 35 inches - not 35.5 inches.

It is often used to describe a type of coaxial cable where the outer conductor is made of solid material like a copper pipe or aluminum pipe instead of flexiable wire. It is usually lower loss than regular coax of the same diameter and is 100 % shielded. The smaller hardline can be bent to some extent like copper water pipe but you have to use a large bending radius.

Unless you can get a trap tuning guide and the exact spacers to
hold the coil and a good grid dip meter you will spend 6 months
trying to get it going. If traps were taken apart it is hope less endeavor.

For a start, establish a common grounding window at the set. They make
a power strip with F connectors that allows the coax and power line to share
a common ground. This helps limit ground paths through the equipment. The
TV and power pack for the antenna should be plugged into the strip.

Install a good whole-house surge arrestor in you breaker box.

Run the TV coax to coaxial ground fixture that is directly grounded at an
outside
ground rod, before the cable enters the house. This should be the same
ground rod used for the home electrical panel and meter box.

This will reduce your chances for damage, but not eliminate it.

> load of nonsense.

The equation is Total Loss = 10 log ((a^2 - |Rho|^2)/(a(1-|Rho|^2))
where a = 10^(ML/10) and Rho = (SWR-1)/(SWR+1)
ML is matched line loss and SWR is at the load.
The equation for the SWR at the source is (a+|Rho|)/a-|Rho|)
Anybody know where these equations came from?

Message-ID: <u37berk80nct82@corp.supernews.com>
Source record: 151667

Does anybody have any experience with the LDG AT-11 MP Auto Antenna Tuner? I just got one, and after the first attempt at tuning the antenna, it fails to give the proper power up indication. When I press the tune button, it seems to find a match, but when I go back to receive, both needles continuously bounce to full scale and back to zero. I'm not sure if it's something I did or if it has a problem from the factory. I can load and tune the antenna using a manual tuner.

Thanks,

Bob WA7VKF

181. Re: Help - Harris RF-3281 Antenna Coupler

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-03 01:27:08 UTC
From: WEMA Account #1 <wema1@wyoming.com>
Message-ID: <3c33b128$1_1@corp.newsgroups.com>
Source record: 151569
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc,uk.radio.amateur

Martin,

I hope this information is of use to you, as your post is a couple of months old. This information is from the Harris service manual

1) The operating Voltage of the unit (PSU requirements)
13.6 VDC +/- 20%, 1.3 Amp typical

2) The tuning range
The operating frequency is 1.6 to 32 MHz

3) The minimum wire / whip length that can be used
1.6 - 32 MHz - Longwire, dipole, and 24-35 ft. whip
2.0 - 32 MHz - 16 ft. whip
4.0 - 32 MHz - 9 ft. whip

4) The maximum transmitter power the ATU will handle
RF input power: 125 watts PEP voice duty, 30 watts average

One item to be aware of when choosing antennas:

"JMP4 must not be installed when the RF-3281 is operating into a whip antenna from 9 to 35 feet long (2.7 to 10.7 meters). This combination may result in an overcurrent condition at low operating frequencies.

"Installing JMP4 configures the antenna coupler matching network for long-wire antennas from 75 to 150 feet (22.9 to 45.7 meters). When the jumper is installed, additional shunt capacitance is added to the antenna connection. THis capacitance is required to overcome the inductive impedence of the long-wire antennas when operated at frequencies where the electrical length of the antenna is between 1/4 and 1/2 wavelength."

Hi All,

Would it be possible to construct a simple portable antenna using just ladder line? What I mean is, could you take 82 feet of 450 ohm ladder line and separate 51 feet to make both halves of the dipole with the rest becoming feedline to a balun and tuner for an instant G5RV? I do a lot of portable operating which means generally very inefficient antennas. I would like to have a simple, easy to carry antenna with a bit more efficiency, especially for emergency situations.

Any opinions would be greatly appreciated.

Determining soil resistivity from samples in the kitchen sink is the correct way of going about it. Some of my most critical measurements have been made in galvanised buckets sitting on the floor. (The buckets, dolt - not me.)

The derived values are, by definition, independent of the size of the sample.

When the sample size is small relative to a wavelength AT THE PROPAGATION VELOCITY IN THE SOIL ITSELF measurement errors due to the dimensions of the test leads are minimised.

Since the measured impedances (not the derived values) must be in the range best accommodated by the impedance measuring instrument there are restrictions on the size and shape of the sample. It follows there are similar restrictions on the measuring instrument itself.

The advent of hand-held 'antenna analysers' has made HF kitchen sink measurements feasible for the amateur. They are the best thing since sliced bread. Can be made better.

It now remains only for antenna analysers to provide the sign of plus or minus jX.

The necessary technology has been available for 10 or so years. Delays in putting such instruments on the market is due solely to the need for manufacturers to introduce the facilities in easy graduated phases, so maximising the profits.

The profit motive has much to answer for ! ;o)

Out of curiosity I decided to do a test using modeling to test this.
The results tend to back up Reg's claims. But I am a bit leary of the
accuracy of the modeling being I can't really test it in the real
world too easy. I decided to start with an average ground.

And here are the numbers...

antenna is a 1/4 vertical on 1.825 mhz. ground dial. 13 , cond 5, NEC4
engine, using 40m long radials "appx 1/4 wave"

DBI TOA in degrees
0 40m radials 1.63 at 22
4 40m radials 2.42 at 22
8 40m radials 2.88 at 22
16 40m radials 3.39 at 20
32 40m radials 3.87 at 18
64 40m radials 4.27 at 14
120 40m radials 4.54 at 12

Now the same, except 20m long half size radials:

DBI TOA in degrees
4 20m radials 2.39 at 22
8 20m radials 2.85 at 22
16 20m radials 3.37 at 20
32 20m radials 3.85 at 18
64 20m radials 4.26 at 14
120 20m radials 4.54 at 12

and with 5m long radials:

DBI TOA in degrees
4 5m radials 2.27 at 22
8 5m radials 2.73 at 22
16 5m radials 3.26 at 20
32 5m radials 3.78 at 18
64 5m radials 4.22 at 16
120 5m radials 4.51 at 12

and just for kicks, 1m long radials:

DBI TOA in degrees
4 1m radials 2.09 at 22
8 1m radials 2.50 at 22
16 1m radials 3.02 at 22
32 1m radials 3.58 at 20
64 1m radials 4.09 at 16
120 1m radials 4.44 at 14

I tried the same tests with mininec and got almost the same results.
So then I decided to try other ground conditions using NEC again.

For the same antenna over "bad" ground of ground dial. 4 , cond 1, I
got these results:

First with 40m long radials:

DBI TOA in degrees
0 40m radials 0.00 at 26 - actually is negative gain...
4 40m radials 1.50 at 28
8 40m radials 2.37 at 24
16 40m radials 3.17 at 22

32 40m radials 3.81 at 18
64 40m radials 4.26 at 16
120 40m radials 4.56 at 12

and with the same bad ground 4/1 and short 1m radials:

DBI TOA in degrees
4 1m radials 0.76 at 28
8 1m radials 1.64 at 28
16 1m radials 2.60 at 24
32 1m radials 3.43 at 22
64 1m radials 4.05 at 18
120 1m radials 4.45 at 14

Now the same antenna and excellent ground of ground dial. 20, cond. 30
and 40m long radials.

DBI TOA in degrees
0 40m radials 3.25 at 16
4 40m radials 3.44 at 16
8 40m radials 3.60 at 16
16 40m radials 3.82 at 16
32 40m radials 4.07 at 16
64 40m radials 4.34 at 14
120 40m radials 4.56 at 12

Now the same antenna and excellent ground of ground dial. 20, cond. 30
and 1m long radials.

DBI TOA in degrees
4 1m radials 3.35 at 18
8 1m radials 3.46 at 18
16 1m radials 3.66 at 16
32 1m radials 3.93 at 16
64 1m radials 4.22 at 14
120 1m radials 4.47 at 12

Now, if this test is accurate, it seems to me the number of radials is
the most important thing regardless of the length. About the only
advantage I can see to the longer radials is the slightly reduced TOA.
And it's barely enough to notice I bet except for maybe the hard core
dx hounds. Note that the 120 radials gives nearly optimum results no
matter the length. Is this a fluke of NEC4, or is this accurate? I did
get the same results using mininec almost to a tee. Hard to say
without being able to test in the real world, but according to the
numbers, Reg seems to be right about long radials being pretty much a
waste of copper for hams anyway. But I also noticed 120 1/4 radials
did give consistant results over any type of ground, so I can
understand why the BC'ers use that many just to be on the safe side.
But then again, I got pretty much the same thing even with the 120 1m
radials. Just a slightly higher TOA than the 40m radials. The gain
itself wouldn't be enough to notice. Before doing this, I wouldn't

have expected the short radials to do near as well as they did. But on the other hand, maybe the modeling is all wet in this regard and I wasted my time...:(Was an interesting exercise though...This was done at 160m. I may try other frequencies later to compare. I don't think the overall results would change too much. Adding 120 3 ft radials to my 160m antenna is something I could get away with. I may try it. If my performance takes a big jump, there may be something to the short radials. I'm only using about 4 1/4 wl radials right now over fairly good ground. So if the modeling is accurate, I should see a noticable difference when adding 120 3 ft radials. If I don't , something is wrong with the NEC engine/model. MK

Rick,
Yes and no. What you described wouldn't be a 'G5RV', but
it should work fine depending on the tuner. If your tuner is
one of the 'built-in' ATUs, it probably won't work all bands.
The common ATU doesn't have much impedance range...
'Doc

This does not validate the process (still undisclosed) and suggests
nothing of being a better way than measurements in situ.

>
>The derived values are, by definition, independent of the size of the

Test leads being part of the System dismiss any such notion of
"error." If you move away from the in situ problem, you must reduce
your variables, but you can never remove the added inaccuracy.

That's like expecting a 3" meter giving you 1% accuracy. Works on a
bridge, but nothing as sophisticated as that has been described.

>
>It now remains only for antenna analysers to provide the sign of plus or
>minus jX.

And as Dr. Johnson would say "the triumph of hope over experience."

Ah Punchinello,

An admirable try, but nothing really said was there?

If you simply gave away the recipe you jealously guard in your
kitchen, the mantle of Old Wife might fall away.

I think I made an error on the program I was using. I don't think it used the NEC4 engine after all. I think it is mininec based also. I had thought I had downloaded the standard NEC-4 program for some reason, and I did a search of all my programs and found a NEC4WIN demo. I made the mistake of assuming that this program was based on NEC-4 being it had that name, but after reading the help file a bit, I think it is also mininec based. So that may be why I'm seeing the things I am. The NEC-4 you mention must be a totally different animal. So anyway, I'm now probably more confused than when I started as I don't know how well mininec deals with various length ground radials...:/ MK

> now!

The normal way to protect an antenna or any other object is to put a
lightning rod slightly above it. And even this is not totally
foolproof. Ben Franklin already devised this many, many , years ago.
Normally, in ham radio you don't "protect" an antenna. You use the
antenna or it's mast as a lightning rod to ground. The less resistance
to ground, the less damage. Only dish owners and such try to protect
their antennas from direct strikes. And the only really sure way is to
put a more attractive lighting rod slightly above it. One with a sharp
point. But like I said, even this is not totally foolproof as
lightning can strike below the tops of structures. But the sharp point
and easy streaming of the lighting rod make this fairly unlikely. You
can drive around Houston on the freeway and see freeway cams every few
blocks that are mounted on tall poles. You will notice on each one,
you will see a curved one piece lightning rod that curves around the
camera from underneath it's grounded base and comes to a sharp point
over the top of the camera. Looks like a big C with a point on top.

Twas a grounded antena...and an elaborate ground system. That ws the only
time I've had an antenna damaged from lightening even though the tower gets
hit two or three times a summer on average. This past summer we didn't get
anything remotely close.

We had one of the big commercial verticals side mounted at 600 feet on a
broadcast tower as part of a comercial installation. It took a direct hit,
even though it was about 300 feet below the top of the tower. It blew that
one all to pieces.

Dear Richard,

I'm surprised you appear unable to solve such a trivial problem in electrical measurements for youself. People have been making conductivity measurements ever since Michael Faraday. And HE didn't have a 259.

Just concentrate on it. Start at DC and work your way up.

I'll give you a clue - if your soil sample is a cube, 39.37 inches along each edge, you can measure conductivity (or resistivity) directly. But your XYL is unlikely to welcome half a ton of damp dirt into the kitchen. ;o)

========================

Cecil,

Your amendments now make sense. They come from elementary transmission line analysis and relate SWR and Reflection Coefficient to each other. They assume line Zo is purely resistive which is reasonable for ordinary lines at HF.

That great man Oliver Heaviside, amateur physicist and mathematician, may have been the first person to write down the formulae in that form around 1870. At the time of the Franco-Prussian war. But In those days there were no ARRL handbooks to publish them in.

As RC goes from 0 to 1, SWR goes from 1 to infinity. If you know what the RC is then you also know the SWR - that is if a long transmission actually exists between meter and transmitter. Otherwise it is necessary to exercise one's imagination of which commodity there is no shortage amongst radio amateurs.

Our SWR meters don't measure SWR, they merely respond to the modulus of the RC and should be scaled linearly from 0 to 1.0 Yes, I know I'm a heretic.

For the exact behaviour of SWR and RC on transmission lines, at any frequency, for any terminating impedance download programs RJELINE3 and 4. Which, incidentally, will also demonstrate the existence on real lines of reflection coeficients much greater than 1.0 Mr Smith's ordinary charts will not admit of such an outrageous idea. ;o)

Program ZL_ZIN does things in reverse. It calculates on real lines what the terminating impedance must be to give a measured line input impedance. It avoids the dangerous hazards involved with taking an impedance bridge up to the centre feedpoint of your horizontal dipole. You will be using the feedline as a very long test lead to the measuring instrument and is another example of a formula preceding the measurement.

Thanks bob for the info. I am a newbie listening to SW radio with a normal cassette deck radio but with a long wire antenna round into a coil which gives me quite a nice reception all the time.

But now i think it has now come for some serious DXing after so many years of listening and that's why i am looking for the antenna which i will have buy for the Yaesu radio. :))

Thanks a lot :)

> should not be too large. Thanks.
>

Don't go spending any large amount of money (or effort) on an antenna to
start with - you will
hear a lot with 5 to 10 metres of wire hooked into the hi-res input on the
back of the '100 - I used
one like that for a long time.

Like most relatively budget prices HF receivers, the front end of the
FRG-100 is pretty wide
and suffers from noise and overloading from strong signals - I tried a
variety of antennas and
found that while putting up more wire boosted the required signal strength,
it also brings up the
noise level, so you often do not gain much. A dipole cut approximately to
frequency seemed to be better than a long wire but you will probably find
that you have some attenuation switched in a
lot of the time.

If you are prepared to spend some money on the antenna side, you are
probably best off
buying (or building) a pre-selector (MFJ make one) to replace some of the
missing front-end
selectivity that used to be built into old valve superhets...

Martin (G8FXC)

Roy Lewallen wrote:
"At least one problem is that it (simplified analysis) doesn`t account for the considerable coupling among radials that takes place."

That puzzled me because I see no relevance.

I went back to Ed Laport who has included much of the findings of Brown, Lewis, and Epstein in his "Radio Antenna Engineering". Sure enough, Laport has an Appendix III-A which is: "Magnitudes of Mutual Impedance Between Identical Thin Vertical Cylindrical Radiators as a Function of Height and Spacing" (After G.H. Brown).

This concerns directional arrays, not ground wires.

Best regards, Richard Harrison, KB5WZI

Roy Lewallen wrote:
"A simplified, but reasonably accurate summary of Brown, Lewis, and Epstein`s conclusions is that if the radials are short, adding more radials doesn`t help a whole lot. And if there are only a few radials, making them longer doesn`t help a lot.

Ed Laport puts his own spin on B, L, & E`s findings on pages 117 and 118 among others of "Radio Antenna Engineering". Incidently, B, L, & E`s work was done at 3 MHz according to Ed Laport.

Beyond 1/2-wavelength, displacement currents captured by radials are negligible.

Beyond 0.4-wavelength, efficiency gain from radial extensions is negligible.

Effective length of radials decreases as their number increases.

B, L, & E found the point of diminishing returns for radials to be 0.4-wavelength and 120 wires. With such a system of radial ground wires they said a perfect earth was approximated.

The FCC was actually lenient in requiring only 120 1/4-wave radials.

Best regards, Richard Harrison, KB5WZI

You may also consider contacting MFJ - I did when I accidentially blew
my MF-259B by applying reverse polarity from the powersupply (I know I
know, stupid...) I emailed their tech-support
(techinfo@mfjenterprises.com), and got all the necessary documents for
free, enabling me to repair and align the analyzer.

Very very good service from MFJ, and I'll certainly recommend them for
their products as well as their support. *** Kudos ***

When the planes were hijacked on Sept. 11, according to reports many people on the plane used cell phones. How do these phones work through the aluminum skin of the aircraft, which seems to surround them completely? I apologize for the ignorance that this question reveals, but I don't have a cell phone and I haven't flow for about ten years.

Yeah. They actually had recordings of the guy's desperate
communications on the show. The guy was somewhat sensible and
sober...the little stunt simply got out of hand.

They don't get through the skin, but they do get through the
windows just fine. The wavelengths are comparable to or less
than the window size, and so the windows present minimal or
no obstacle.

Holding the cellphone near an airplane window allows the RF to escape.

Roger, K8RI wrote:
"We had one of the big commercial verticals side mounted on a broadcast tower as a part of a commercial installation. It took a direct hit even though it was about 300 feet below the top of the tower. It blew that one all to pieces."

We standardized early on with Andrew stainless folded monopoles because they were never seriously damaged by lightning. Antenna vendors were always trying to sell us something that was cheaper, performed better, or had some other advantages. During 26 years at that company, I never saw a successful replacement for the Andrew.

Vendors often would try to sell us some fibergless thingie. Even fiberglass parabolas to replace aluminum. I saw no reason to try a fiberglass dish. Aluminum dishes worked very well for us. But, we did try a fiberglass 33 MHz tubular thing wrapped with wire. It turned out like Roger`s antenna. It looked like a giant cigar that had exploded on being hit by lightning. No problem when we put the old Andrew back at the top of the tower.

Best regards, Richard Harrison, KB5WZI

They didn't use cell phones. They used the in-flight phones mounted in the seat backs. These are wired into the aircraft and to an antenna on the outside of the fuselage.

They couldn't have used a cell phone due to the interference it would have caused being in range of so many towers. The cell phones wouldn't have worked.

Mark Keith wrote:
"But they have to be somewhat green and have moisture in them to be able to conduct."

Ohm prevails. It`s a matter of volts. In 1949 when KPRC and KXYZ shared a radio tower, we used to measure the antenna currents of each station regularly. The tower was built for KTRH, 740 KHz. It was hot for KPRC at 950 KHz and even hotter for KXYZ at 1320 KHz. We had a long wood stick with a bent nail in one end to operate the ammeter shorting switches. Every few weeks we had to replace the stick which quickly developed a carbonized groove between the nail and the operator`s hand. The groove lit up with sparks on every switch operation with growing intensity.

Then, at the SW broadcast plant where I worked, birds trying to land on the 600-ohm transmission lines carrying 100 KW simply evaporated in a plume of flame. So, it`s just a question of enough volts to light a fire.

Martin

I was wondering if you are speaking from personal experience with the FRG 100
or just "what you have heard". Because my experience with the FRG 100 does not
reflect this statement at all. I have one and I also have all kinds of commercial broadcast
towers around me, one as close as 1000' from my house. I have a state police repeater
tower about as close, and all kinds of pager and what not antennas close to me. I have
yet to have any images show up on mine. Not even any A.M. station crosstalk when I'm
in the A.M. band. My experience with the FRG 100 is that it has a pretty good front end
and is quite sensitive. I will agree with your first statement that all you need is about
10
to 15 meters of wire and a good earth grd.

Jeff

First, thanks to all who responded with comments and suggestions.

Bill,

I do get WNJT-DT from behind the hill, but it is not strong enough. The Longley-Rice method and the GLOBE terrain database (1 KM resolution) predicts the point to point pathloss between isotropic radiators to be 178db for a 90% confidence and a reliability of 90%; yielding a 2db signal to noise ratio over a 6mhz bandwidth. The ATSC 8VSB modulation method requires about 15 db signal to noise ratio for acceptable picture. A 17 dbi antenna might just work, but a 20+ dbi antenna gain will provide a better margin. My testing with a RadioShack 100" UHF only antenna did not show any surprises as the height was adjusted. My plan is to build the 17.5dbi antenna and test the results. If more gain is needed then I'll go by your suggestion and stack another antenna. It will be interesting to see if all this computer simulation is useful. Again, Thanks.

Robert

Hi Bob,

From the air, the cell phone can see several cell's antennas. Each
combines in a network that helps for local roaming. To connect at
several at once with nearly equal power (almost certain from the air)
is probably rejected by the system (as it would certainly confuse
which cell "owned" the connection and cause them to go into an
infinite reconnect protocol - which is otherwise known as collision
resolution.)

Lee,
I'd try a loop antenna fed with ladder line. As large as
I could make it, and as high as I could get it. Feed it through
a good tuner, and you can make it 'go' anywhere, and even realize
some gain out of it on some frequencies. Not ~the~ best antenna
for all bands, but it does remarkably well on most of them.
'Doc

I have one mounted on my roof. I thought it was a pretty good antenna - a lot better than my Cushcraft R7000. That is, until I put up a 102 foot wire antenna at 60 feet in the trees. It is a top fed L with one side horizontal and the other vertical. Center fed with ladder line through a tuner, it beats the vertical on all bands and with a lot less noise.

Just a thought.

237. Status of NFPA Lightning Protection Code?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-04 03:55:42 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c352b71_3@news1.prserv.net>
Source record: 151523

The ongoing questions about lightning protection prompt me to ask the following: NFPA used to issue a Lightning Protection Code, NFPA 78, but it has not appeared in their catalog for many years. The most recent version I have been able to turn up is dated in the early 90s, which is way out of date for an NFPA code. For a short time it was included in the Building Construction Codes, but then it also disappeared from there. I heard (urban legend?) that there had been a great deal of disagreement inside the committee which was to update it, and that some technical data has been developed which tends to refute some of the premises of the existing code, causing NFPA to let it expire and wait for some other agency to issue a new lightning protection code. Anyone have any factual information on this? Maybe it was reissued under a different number?

Doc's got a good idea with the loop. I have had very good results from a top fed inverted L. The center is at 60 feet with 51 feet horizontal and 51 feet vertical. Fed with ladder line through a tuner. Check out Cebik's website http://www.cebik.com/ for an education on antennas including the top fed L.

Wellllll, I don't disagree with what Richard and Ken have said, that the cell phones don't work properly at elevations above 5000 feet; but I seem to recall that the hijackers were flying low on the flights toward Washington to avoid radar, which means callers on the flights may have been low enough to pick up individual cell towers while using their personal cell phones...

Yes, they certainly are. Soil is not homogeneous like copper.

>But regarding independence of G and K of depth, the depth I referred to was
>not the depth of the soil below the surface but the depth of penetration of
>3 MHz radio waves.

The topsoil layer is from 9 to 12 inches in cultivated areas. Below that is hardpan,
compacted and relatively lacking in organic matter, undisturbed for 100 years
or more. Deeper still, about 3 feet and greater, is the true subsoil, which is even
more compacted, and containing negligible organic matter (in nonforested areas).
This has been undisturbed for thousands of years. Below that is rock, granite here,
limestone up at my farm (the exact depth down to rock varies. It can be as much
as 50 feet in some areas, darn near the surface in others).

Skin depth at 3 MHz is roughly 12 to 20 feet depending on the exact composition,
moisture content, and thickness of these layers. Note it requires several skin depths
to reduce a RF signal down to negligible levels.

Didn't take very long really. Maybe 20-30 min. I'm still wondering about the results. I expect there is a "hook" somewhere in the results of the short radials. But there is no doubt the area beneath the antenna is the most critical place for copper. I was confused on the NEC-4 and the name of the NEC4WIN program. I assumed it used that engine with that name it has. I had downloaded it months ago, and had never tried it yet. I am going to try a set of 120 short radials on my 160 inv L but I want to do some tests first to find out where I stand now to make a fairly accurate comparison. Even 120 3 ft radials is a bit of wire to cut and lay out. Will take a while. I could make a mat of chicken wire or whatever, but I worry about the crossweaving of the wires. With all the wires extending out normally from the antenna, you would have a higher density of copper at the antenna compared to chicken wire which would be the same everywhere. I think I'd be better off with normal copper radials. I have two 160 antennas right now. A T and an L. The T is usually best, but if the radials did as well as modeled, it should be enough to push the L into the lead. Or I would think anyway. If it doesn't pan out, something is wrong with the short radial theory. What makes me suspicious is that no one has really touted large amounts of short radials in the past to get near optimum results. "4.5 dbi range" Surely this has already been tested I would think. I have no idea really, but I do know they have been doing a lot of
testing on actual mock houses etc, to find the best ways to protect
them. I taped a TV program that showed them doing it. They fire
rockets up over the house with leader wires and zap em. They had a
house all set up with electric wiring, TV's, Phones, etc, etc to find
out the weak spots I guess. They may be waiting for some of that data.
Seems it could be pretty valuable I bet. They have been doing a lot of
lightning research since the early 90's. Out in New Mexico, etc.
It may well be time for an update. MK

> Best regards, Richard Harrison, KB5WZI

I guess some trees are better than others. I've never seen one actually light on fire here though. I've only seen the branch scorching once when I had the bare wire end tangling though the tree branch. I was running about 1300-1400 w when I did that. I had never had a problem with it before, or with it since though at normal ham power levels though. The insulated wire seems to nip it in the bud fairly well even though you would think the high voltage would punch through the 600v rated plastic. About the closest to fireworks I've ever had was when one leg of my 40 dipole fell down on my grounded guy wire, and I was talking for a good while and didn't notice it. I had someone knock on the door all excited that I had a fire on my roof. It must have made huge sparks. I was doing a KW plus at that time also. I would't have noticed if they hadn't said anything. The amp didn't flinch. I'm surprised it didn't bark and spark at me in disgust. But it just kept on humming along. :) I need to get it going again before the tubes totally gas up on me. I've got it partially dismantled and I want to put new caps in it before I put it back together. It's been sitting so long I'm going to burn the tubes in again a day or two before I put high voltage to it. I really want to buy or build a solid state amp for my 706. I only need about 500w for average everyday use. But I like the henry as a match for my 830. Good pair...A good tree fryer too. MK

246. Lightening ?

Source record: 151532

What sort of protection, if any, do people use against lightening striking the antenna ?
I must admit I have never heard of this happening but there does seem to be quite a lot of gear out there such as Gas Surge Protectors which the adverts say are ' vital '.
Are they necessary ? do they work ? Doesn't just unplugging the antenna still leave the problem of the current being able to enter the house ? Would a switcher box with a 'spare' connection connected to earth be of use ?

From: ve3ab@mondenet.ca
Message-ID: <3c357aad.1463140@news.mondenet.com>
Source record: 151534

I just got my tower up before the snow fell this year and the beam
will have to wait till spring..but the wire antenna i put up..the
windom style antenna i put up is getting out real well for me.
With 100 w from my diminutive atlas 210x I got some 20 and 25 over
reports on 20m ssb. Was working and heard JA(off the long end
wire).must have some directivity off that end particulary on 10 mtrs.
10 mtrs works fb as well.
I use a Johnsons match box and about 50 ft of 450 ohm ladder line
(#14 guage stranded hd stuff). With the johnsons match box..
I dont always get a perfect 1.1 to 1 swr..sometimes 1.5 to 1 in that
range of a dip..but the rig likes it and it gets out well.
I was tempted to drop the two ends as verticals and have a 66 ft
flattop..thus creating a half square type antenna fed off center..but
the trees werent in the right location. (from what ive been
reading..this configuration works fb too..) 73 Earl VE3ab

248. Re: Best Antenna for FRG-100

Source record: 151533

Yes, I am talking from personal experience, but don't get me wrong - I was not
trying to imply that the FRG-100 is a poor receiver - I am very fond of mine! The fact
does remain that, like most modern mid-priced boxes, it has very little front-end
selectivity - if you check the circuit diagram, you will find that it just switches in one
of about half a dozen different band-pass filters as you tune around. The old generation
of valved superhets usually had some measure of tuning in the front-end - oh for
multi-gang variable capacitors!

When I first got mine, in a hurry to try it out I just hooked a few metres of wire into the hi-res
input and played - it worked great!. Later, I decided to get more serious about antennas
and started putting up more and more wire in more complex configurations. You soon
reach a point (at least on the lower frequencies) where each extra bit of wire raises the
noise level by near enough as much as it raises the signal level. Its not cross-talk in the
sense that you hear strong adjacent signals splattering through - its just a general high
noise floor which, I have read, is a symptom of overloading in the front-end - if anyone
knows better, I am prepared to stand corrected!

It is worth noting that most of the local signal sources you mention are VHF or higher.
I have seen it said on a number of occasions that the situation for SW reception in
Europe is rather different than it is for the US - we tend to have a higher concentration
of local MW and HF stations than you guys!

251. Re: Lots of land and lots of wire

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-04 11:56:21 UTC
From: Joe O <jenjoeo@zianet.com>
Message-ID: <3c359aa1.0@oracle.zianet.com>
Source record: 151539

I concur that a large horizontal loop is a good start. I have a 480 ft loop up at 35 ft and I often work JA/ZL on 12 Meters(Low angle of radiation). On 75/40 I have been told that my signal is exceptionally strong on State/regional nets(High Angle of radiation).
For a second antenna I suggest a full wave vertical loop for 40 M. Feed the loops with open/ladder line , extend to as close to the shack as possible then a current balun and low loss coax into the building . End the transmission line with a High Power ATU.
I love loops.

Hi Max,
Check for the StealthII-2.5/40 at
http://www.qth.com/hiqantennas/
or
http://www.qth.com/stealthantennas/
It is a nice and sleek looking yet rugged and high quality
screwdriver.
You can run 1 kW with this antenna.
I have very good experience with the Stealth II-3 antenna. They are
not the cheapest on the market but as always, you get what you pay for
and Charlie is very easy to deal with.
Check also http://www.eham.net/reviews/detail/1452
Good luck and happy mobiling!

"Skin depth at 3 MHz is roughly 12 to 20 feet depending on the exact composition, moisture content, and thickness of these layers. Note it requires several skin depths to reduce a RF signal dowen to negligible levels."

Good to hear from Gary again. I`ve missed his informed contributions for awhile.

RF soil penetration (skin depth) is where current has fallen to 1/e of the surface current, or 37%. Depth declines as the reciprocal of the square root of frequency. 90% of loss is within one skin depth.

Best regards, Richard Harrison, KB5WZI

I've looked at that formula a little closer. The elementary terms in the formula are a=(Pin/Pout) for a matched line and Rho^2=(P-/P+) for a line with standing waves. Now it makes sense.

Source record: 151544

Mark Keith wroote:
"Even 120 3-ft radials is a lot of wire to cut and lay out."

The broadcast stations I`ve worked in used sheets of copper around their towers for radial connections. Current density is greatest at the tower. Any resistance here produces the greatest loss. Eddy currents are possible in solid copper which allows lateral conduction in addition to radial conduction but the conductivity is so high that eddy current loss is low.

Using the wire you have in shorter lengths to provide more radials has proved to be more efficient in manycases, Broadcast ground system designers are aware of this but the FCC says at least 120 1/4-wave radials so the designer complies. Many designers add another 120 short radials interspersed with the 1/4-wave radials as they want the biggest signal they can get. The FCC stipulates minimum requirements.

Brown, Lewis, and Epstein reported in 1937 that the effective length of radials decreases as the number of radials decreases. The converse would also be true. More radials means more effective length for the radials.

Best regards, Richard Harrison, KB5WZI

257. 30m delta loop issues

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-04 14:31:57 UTC

I use a delta loop on 80/40m and added 30m yesterday. 80/40m both have very low swr and are fairly broad.

However, the 30m loop is not cooperating. Its bandwidth is very narrow and swr is 3:1 at resonant freq. The analyzer doesn't show anything abby normal either ....

Any ideas as to why this particular loop and band is behaving this way?

Maybe not, but a little extra effort sure can save your equipment, and
maybe even your life. Where do you think that a couple million amps of
electric current will go once it gets to the end of the coax laying at your
feet ?

I wrote:
"Depth declines as the reciprocal of the square root of frequency."

I meant that depth decreases as frequency increases, but only as the square root of the frequency. Here is the formula for skin depth in meters (S).

S = 1 / sq rt 4pi times frequency times permeability times 10,000

Permeability is in electromagnetic units.

Frequency is in Hertz.

Skin depth is 1/2 the wavelength of the r-f`s velocity in the soil, for whatever that is worth.

Of course, assuming you are feeding them in parallel. Your 80m loop,
being operated near its third harmonic, is soaking up enough of your
signal on 30m to affect the impedance. Third harmonic responses often
upset paralleled elements. 80m/30m, 40m/15m, and 30m/10m are the
usual HF gotchas.

You`re not quite as vulnerable as old Ben Franklin flying his Kite.

I hope my feet won`t be in the lightning`s path. The shorter path to ground is at my feet, but under the coax, and I hope it is more attractive. The flash may still burn my shoes off.

A drain for lightning on the coax should have been made outside the building.

The broadcast stations I`ve worked in used coax, openwire lines, and skeletal coax wirelines.

Coax was either buried or grounded at both ends and/or multiple points.

The openwire lines were protected with arc-gaps at both ends.

The skeletal coax was supported by many poles topped with brackets to maintain spacing for the wires forming the "coax". Each support pole was buried to a considerable depth and the outer wires of the "coax" were directly clamped to the bracket.

None of these transmission lines ever let a trace of lightning into the insideplant.

Best regards, Richard Harrison, KB5WZI

Unless numbers are forthcoming in these supposed erudite newsgroup messages they are nothing more than a collection of bafflegabs usually associated with fractals, cross-fields, EH, amps in the middle of dipoles, SWR on non-existent transmission lines, conjugate matches, etc.

It is a fact, in 1937, a measurement of the vitally important ground resistivity was omitted because none of the trio had a clear idea of what it was all about. It was just a job to find employment. When the money and wire ran out they stopped. Nothing wrong with that! That's the normal state of affairs on this planet.

Again I say, do not decry the very practical value of their work at that time in the evolution of radio broadcasting. But we should not use their results to draw conclusions they, themselves, did not conclude. Particularly we should be careful about extending their results to other parts of the spectrum used by us amateurs. Their papers do not constitute a bible and they are neither disciples nor the three wise men.

A vast amount of practical information has been accumulated since 1937, most of it just logical common sense, economics and statistics (much neglected subjects) which apply just as much to amateurs as they do to broadcasters of soap.

I am everlastingly dumfounded by the use of high-technology satellite and light-fibre communication systems just to sell germ-free toilet cleansers.

But they who own and control the world's communications circuits and systems, satellite, terrestrial, analogue, digital, LF & VHF radio, interactive TV, telephone, internet, will rule this Earth.

Astro

Although in most cases cellphones are inoperable while flying above the 1 mile mark, the airliners that were hijacked were flying very low to avoid radar and there were celltowers located atop the WTC buildings to provide adequate service to those in nearby skyscrapers.

It is not unfeasible at all for a cellphone to work from a commercial airliner at low altitude, especially an airliner that is approaching below the height of the antenna.

It also depends upon which cellphones you are talking about, their output power and the location of that companies celltower.

Hi Earl.
Sounds like you got a good antenna there.
I have a Doublet fed with 400 ohm (home brew) and by a Johnson Matchbox.

If my rig loads I am happy, but I could not load it on 30, so I was not happy.

I read the stuff on W4RNL web site (cebik.com) and added an additional variable cap to
my Matchbox. It now matches all bands well.

KA9CAR at arrl dot net.

Richard has it right - it has to do with multiple sites picking up the signal. Someone else said if you were above 5000' they wouldn't work - kinda sorta, but not really - otherwise nobody in Denver would be able to use a cell phone!

Some switches will drop a call if multiple towers on the same system get a signal from the same ecn. Most do not - thus allowing the call to go through. The cell biz bullied the FCC into making it illegal to use phones inflight because they don't want to tie up multiple towers/circuits.

fwiw.

For 6-meters you might have enough room to swing a small beam. For 10
and 20 just use dipoles. You could even feed them at a common point
with just one feedline. Another thought would be to use an automatic
antenna tuner, like SGC, Icom, etc. and end feed a wire antenna.
Don't know how you would get back to ground. Depends on your
building's construction.

> S = 1 / sq rt 4pi times frequency times permeability times 10,000
>
> Permeability is in electromagnetic units.
>
> Frequency is in Hertz.

I am no longer familiar with the electromagnetic system of units but I think they are essentially a scaled version of CGS. Of course most engineering these days uses the MKS system of units which has some significant differences when it comes to electromagnetic calculations. Either way, your equation for skin depth is not generally true since it does not account for permitivity or conductivity.

Conventionally, the skin depth is defined as the depth where the magnitude of the current density has decayed to 1/e of the surface value. This is numerically equal to the reciprocal of the real part of the propagation constant.

The propagation constant, gamma = alpha + j * beta.

The real part, alpha, is the attenuation in nepers per unit distance and is the reciprocal of the conventional skin depth.

The imaginary part, beta, is the phase constant in radians per unit distance.

(MKS system of units)

gamma = sqrt(j*omega * sqrt(mu * epsilon) * sqrt(1 - j* sigma/(omega * epsilon))

omega is the angular frequency in radians / second
mu is the permeability in Henrys / meter
epsilon is the permitivity in Farads / meter
sigma is the bulk conductivity in Siemens / meter

In the special case of a good conductor, that is when sigma / (omega * epsilon) >> 1 ,
or in another words, displacement current is negligible compared to

conduction current, the skin
depth equals:

delta = 1/sqrt(pi * f * mu * sigma)

where:

delta is the skin depth in meters
f is the frequency in Hertz = 2 * pi * omega

Typical soils have a value of sigma/(omega*epsilon) ranging from less
than one to 20 or so. Solid rock can be much smaller making it
inadvisable to use the good conductor approximations without carefully
determining the applicability of the approximations and the
consequences of misuse.

> Skin depth is 1/2 the wavelength of the r-f`s velocity in the soil, for
> whatever that is worth.

From the above conventional definition, the wavelength of a plane wave
propagating in the medium is equal to 2 * pi / beta. In the case of a
good conductor where alpha = beta (approximately), then the wavelength
is equal to 2 * pi * delta, not 2 * delta as you claim. I would be
very surprised if this discrepancy was the result of using EMU instead
of MKS. The difference in systems of units does explain for a factor
of sqrt(4) and the different scaling of mu and epsilon, but not the
relationship between skin depth and wavelength.

275. AM reception HELP !!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-04 19:04:39 UTC
From: Alex <alex99@peoplepc.com>
Message-ID: <a14u8c$q665@eccws12.dearborn.ford.com>
Source record: 151565

Help! I work in an office building in the Detroit area and listen to an am/fm extended range radio. I try to listen to various am stations but either don't get them or they come in very poor with a lot of hissing/crackling noise. If I bring the radio close to a window, reception is perfect. Unfortunately I sit about 25 feet from a window and CAN'T bring my radio any closer.

Can anyone offer suggestions on how to improve my reception and get rid of some of the hissing/crackling????

Ah Punchinello!

Your surprise is delightfully manufactured to the highest of
specifications.

Your Faraday reference is a wonderful example of neo-classical grave
robbing: dressing up the corpse as citation, another one of those
amusing Old Wive's habits that struggles for the appearance of
respectability.

And did we get a clue as to this veiled mystery process that is so
much better than direct measure? Noooo, I don't think so.

I look at the quote above and it doesn't really say anything does it?
You don't respond to those superior methods you are writing through,
so apparently there is no critique nor downside in them that you can
offer in technical rebuttal. Yet, still and all there is your mumbled
tale for children and small animals of a "better way." It has all of
the appeal of the old Stalinist dogma - or the church's promise of
eventual reward. ALL are best left outside the laboratory door as
these tales are generally served around a warm stove in the kitchen.

Our Little Old Wife jealously huddles over her cache of recipes in her
domain of the kitchen. As we approach to look, they are suddenly
swept under her apron. What appears to be a steaming bucket full of
mud awaits analysis - or are those cookies baked for the kids?

Who can tell, Faraday? (See? I can lift his arm and make him look
like he's waving back at you Punchinello!)

278. What will work for QRP?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-04 19:54:49 UTC
From: blair thompson <blairt@shaw.ca>
Message-ID: <3i1c3us1ad99klcrd6jarkb1l6bi8cur91@4ax.com>
Source record: 151564

I lurk about this list, and also scan the QRP-L archives and
am wondering what I really need to join this select cabal, at least to
participate in their Cub fox hunts, which seem like great fun. I
posted this same question on the QRP-Canada list, but didn't get back
any real antenna suggestions.
I operate CW only and make most contacts at 10W with my TS-50.
I've worked some DX from 10-50 watts. On my hard drive are
instructions for turning the TS-50 down to 5W, which I will do one
of these days. My limitations are in my antenna, I think.
I live in a townhome and run a 100 ' end-fed wire (about as
thick as hook-up wire) out a second-storey window, over the roof to a
Ponderosa Pine tree. At its highest point, it is only up about 23
feet. I have a single 100' counterpoise and can operate on most bands
using an MFJ 949D. It's nice living alone, because it enables me to
snake that 100' counterpoise all over the floor of 3 rooms without any
XYL QRN :)
I monitor on CubFox nights, and also those blisteringly-quick
operators during the regular Fox hunts(Thursdays), but I only
occasionally can hear much action (fox or hounds) which is kinda
frustrating. I presume some of my problems originate with the low
elevation of my wire, but could it also have something to do with
being way out here on the "wet" coast (British Columbia)? Should I try
a resonant counterpoise wire, for the bands I want to work,
especially, 40M (foxhunt), or would that be a waste of time?
My antenna is sort of stealthy, and I would like to keep it
that way (my townhouse is an end-unit). So, I guess my question to
this list would be: does anyone have any suggestions for a better
antenna for QRP operations? An indoor "attic" wire is not an option,
but I'm not averse to some sort of quick, up-and-down, portable,
outdoor-indoor thingie, provided band-switching isn't too much of a
hassle. The convenience of that end-fed tuner antenna has spoilt me :)
Thanks for listening.

Source record: 151567

Alex,
The 'easy' answer is to get promoted to a corner office. The
more realistic(?) answer is that you probably aren't going to be
able to do anything without the cooperation of the business or
the
building's owners. If you can get that 'permission', you have
several options ranging from running a wire to, and out of the
nearest window, to some type of 'active' antenna.
Good luck...
'Doc

Dan,
I guess it depends on the size of your attic. The
possibilities
run from a random length wire to a small beam. Probably the
'easiest'
antenna would be dipoles on each band. The dipoles would negate
the
need for a ground to a large extent too. What would be 'best'?
Beats
me, you'll have to try them to find out...

StarGazer,
Unless your running quite a bit of power, an antenna fire
is one of the last things in the world I'd worry about. They
just don't happen that often. After 20 years in the fire
service, I have never heard of an antenna fire (other than from
lightning).
But to answer your question, 3 feet should be plenty of
separation...

Source record: 151472

Rich,
Lightning protection isn't as 'vital' as you may think. That
does not mean that it isn't desirable, though! The gas-dischange
protectors are good (but expensive) and naturally should be
mounted
out side of the house. The old 'spark-gap' protectors are next
to
useless. By the time they do discharge a surge, the surge has
already reached your equipment. Disconnecting the antenna and
putting
the end of the feedline outside is probably the simplest
protection.
Putting the end of the feed line in a glass jar is as bad as not
disconnecting to start with. For 'small' surges it's okay, but
if
you should ever have a 'for real' lightning strike, the jar makes
a very nice hand grenade (hope your not in the room)! Using an
antenna
switch box that shorts the antennas when not in use is probably
the
most 'common' lightning protection. And it works to an extent,
but
still isn't the 'best' alternative. In most cases, nothing will
stop a direct lightning strike, but ~anything~ might 'help'.
'Doc

>and
>am considering an antenna solution in my attic - it will be completely
>enclosed and shielded by a standard new construction roof >(wood, shingles-but
no metal).

Ended up with a similar situation...got my ticket after buying a house in a similarly restricted neighborhood...the 6M J-Pole holds a birdhouse (not a SINGLE word from the neighbors so far!! or from the birds, for that matter) and got a G5RV (yea, I know...not the best but ya work with what you have) for the attic. The attic is long enough to hold the majority of the G5RV, the ends drop down off the side of the house (two story and on side of hill) towards the low side of the house. Loads FB on 6M, works well on 10/15/20, haven't tried 40/80 (for those that care, my bro's a General class licensee, I'm currently Tech).

A 2M 5 element beam is mounted in the rafters with a 440 yagi underneath, TV rotator to swing them. Seems to work well. As it is suspended below the G5RV, I was concerned about RF problems, but so far no major interference. Separation is at maximum 8 feet, so it is close. When my brother is using the old FTdx560, I disconnect the 2/440 antennas.

My setup is N/S oriented, have worked South America on 10 watts on 6M, my brother had a nice chat with a Uruguayian station the other day, 5/9+ from the old Ftdx560. Not a tribander, but works.

Cheers;
Andrew

I would think one inch would be plenty. You are talking about
something that is fairly rare really. At least to get to the "flames"
level. I've run wire antennas though trees, touching trees in many
places, and running high power amps for years. I rarely see any
problems with this. Actually, only once and it never got close to
flames because the branch was too green. And if you do, it's usually
only at the ends. As long as the antenna is not actually touching
branches at the ends with bare wire, you should be ok. I always try to
keep the ends clear of branches. The rest of the antenna, I don't even
worry about. MK

Source record: 151477

Hi Joe

I'm in a similar situation to Lee (the original poster) - although I've only got _one_ acre to play with - rather than his 40!

I'm trying to keep amateur RF away from the domestic TV aerials - and the one acre I've got is up behind the bungalow - so a centre-fed doublet multi-band with ladder feeder (which I've used before) isn't going to be very easy to do.

I was thinking of an end-fed wire, fed as a zepp - but your suggestion of a loop has got me thinking....

The field is about 90m long by 30m wide - do you think it would be better to go for a 'square' horizontal loop (say 120m total) - or just go for as much wire as possible (which would be rectangular). It'd be most convenient to feed it at a corner with ladder line...

Thanks
Adrian G0THW

Bart caught me. Thanks Bart.
Frequency, permitivity, and conductivity all reduce r-f penetration into the soil (skin depth).
I omitted the conductivity as a multiplier in the denominator.
Sorry.

>is perfect. Unfortunately I sit about 25 feet from a window and CAN'T bring
>my radio any closer.

>Can anyone offer suggestions on how to improve my reception and get rid of
>some of the hissing/crackling????

In the old days of TV before satellite dishes and so on, people in the
mountains who lived down the hill sometimes could do this! They could
put up a decent antenna on TOP the hill that looked at the TV station!
Then they could couple it to a low loss feed line. Then they could put
up another antenna on the downhill side that looked at THEM. They would
tie it to that same feed line that went to the antenna which could see
the TV station that was 'visible' from the hill top, but not down in
the valley!

Now this is pure speculation! Before you give up on life, you MIGHT be
able to tape a decent antenna to the window! You just might be able to
tie it to a decent feed line and then go back to where you are and
either tie it directly to that extended receiver - or - play the TV game
and fire it toward you inside the building with another decent antenna
going back toward you. Frankly, I sorta doubt that the two antenna deal
with the joint feed line will help, but one that fed your BC receiver
directly to antenna terminals on it would do WONDERS for you I bet.

I do admit that the TV games I know about were played with what are
called rhombics and no, ain't *NO* way that's ever going to happen to
you at AM broadcast frequencies! They would be likely to be bigger than
your building at hundreds of feet on a side for rhombics for AM radio!

But putting some metal up there or even a very good loopstick in the
window and running a feed line to it to your radio will make a huge
difference!

Good luck!

Ask the Bryan, Texas power line worker who was working on elevating the 69KV primary mains down Texas Ave., in Bryan two weeks ago! They are moving that line up from about 60 feet on wood poles to about 80 feet on concrete poles! He was a bucket rider and all that, but either let one leg of it brush a ground lead or on a lower voltage 6900 volt bus. The paper said it was against a ground lead.

He was treated and released at one of the local hospitals here for a MASSIVE case of what was just like sunburn! The plasma arc is sorta like getting close to the bolt, but not being hit by it!

Insurance paid for the first two rebuilds of the sister AM station at
Lufkin, Texas. However on the third strike, it also burned the building
down and the insurance boys refused to pay off!

So it went dark.

In each of the three cases, it came in on the POWER mains and went back
out to the antenna ground system. Not the other way around. The site
was in a strange, I am told, physical location. I never actually got to
see the whole deal, only know about it from him. Long before that I
used to be the chief enginner there..

Lightning research has been going on since Ben Franklin. The problem is that much of it is not scientifically based, and rarely is it properly instrumented. Who, for example, was performing the "research" you saw on TV? I know many researchers who will not allow entertainment media to even observe normal scientific experiments because they never understand it and always mis-report it. To restate the question, were the experiments being conducted by a committee or sub-committee of the standards writing branch of the National Fire Protection Association, or some other equally recognized standards writing organization?

I might casually mention that the organization I used to work for did extensive lightning exposure research for NASA in the 70s and early 80s in New Mexico (altitude), Florida (lots of strikes), and Mississippi (the site was cheap). It was used to develop the launch/don't launch criteria now in use at the Cape. But none of it was ever on TV. And, since the goal was to develop software to predict strikes from static field measurements, NO work was done on protection techniques or hardware. NASA did that in-house.

Speaking as one Canadian ham, I understand perfectly your point. The daily Trans-Provincial net on 7.055 is one example. But quite a few US hams check in on CW. I myself don't check into nets or use voice in any portion of an HF CW segment, but the Canadian hams aren't the ones to be pissed off at, it is the Canadian Ministry of Transportation and Communications. Yes we have more voice priveledges than many other ham nations, but it isn't the doing of the hams themselves.

Here's a cheap choke balun. Run your coax through a plastic tube, say 2-3 inches in diameter, 9-10 inches long. Stuff tube with fine steel wool, keeping coax in the centre of the tube. It works! You're welcome! 73. harry, VE3GRO

Hi Pete,

A number of years ago, I reviewed the preliminary survey of a direct lightning hit on a 50KW tower near Portland, OR. The coax had three inch holes in it at every point where it was adjacent to a cross beam. The lighting system had melted. Much of the paint was gone, and many of the guylines were reduced to marbles or completely disappeared. The transmitter was toast, and they were still checking to see if any of the auxiliary equipment would even power up.

When I asked the engineer about the radials I thought he was going to cry. He hadn't even thought to check them. I didn't want to be there when he did.

Fortunately, no one was close to it when the lightning struck, so there were no injuries. They were off the air for several months.

Hi Lee,

If you want some directional capabilities, end fed rhombics are quite
useful. Ladder line to one point, and a 50 ohm load at the opposite
point. If I remember correctly from my days at Lualualei (NAVCOMSTA
Honolulu) they each covered about 60 degrees of arc. So we had six
sets circling each building. They were a couple hundred feet from feed
point to load, but only 15 - 20 feet off the ground, and could be
tuned across the full 2-30MHz short wave band.

Of course we were using 10 and 40 KW transmitters, but we didn't
actually need full power most of the time.

> N2SPP

I remember you guys!

I put in a buried seismic alarm system just on the other side of the road
from your western fenceline.
Had a fun time filtering out your transmitter. :)

I used to get interesting tone sequences, just at the edge of my hearing,
over open inputs on my stereo too.
I always figured they were coming from your rigs.

Rumour had it the VLF output was 1MW.

When were you there? I was there from 72 through 87.

I suppose that every AM broadcast station has two or three backups for every piece of gear and expect to replace them several times a year? It would get a little expensive, wouldn't it. Yes, a station can be protected. It is a lot of work and attention to detail is mandatory but it can be, and is, done.

You can use 2 hamsticks per band mounted horizontally feed end to feed
end by bolting 2 of the mirror mount style mounts together and feed
the contraption like a 1/2 wave dipole... kind of a shortened dipole.

Personally, for ease of installation with minimum equipment... I'de go
with a full size 1/2 wave dipole cut for the lowest band I was going
to operate and use a tuner to help it out on the other bands.

This idea got published a few years back and has persists despite the fact that it never really worked. Had the author tested his premise with a common-mode current meter, he might have suggested something else.

Several decades ago, when working as a broadcast "engineer" with an old time 1st Phone License, had a big, sudden, lightning storm. This was a two tower, 1 kw AM station. The CB on the transmitter were, apparently, set too tight. Every time a tower would get hit, the power to the transmitter (lovely 813s) would pop. I would pop it right back on and away we would go. Got so I would look out the window and wait for a stroke to hit and then pop the breaker. ---No lasting damage resulted.

Bad part of the job was disposing of roasted mice that got across the current meters at the base of each tower. Had to go out and read the meters, which you had to put inline, several times a day. This is a trade that has about disappeared. What a job for an underage fellow (Federal, not State employment rules) to have. What characters I did see! What sort of well paying job could a fellow get today?
I love RF. 73 Mac N8TT
P.S. My antennas have elaborate earthing systems in place. I still keep fingers crossed.

As much wire as possible because then you can operate the lower frequencies
with a more respectable signal.

The formula for overall length for all 4 sides (quad loop) or 3 sides (delta
loop) and mounting it horizontal is fine is

1005 divided by the frequency.

e.g. 1005/1.850 equals 543 feet for a 1 wavelenth loop
divided by 4 which equals 135 feet 9 inches per side
for a quad loop. This is a large 160 meter loop but you should always
make it as big as possible for the lowest frequency you want a good signal
on.

Also, run the coax as straight down and possible from the feed point as you
can and the coax becomes a vertical antenna also.

Try moving the antenna around both horizontally and vertically. Sometimes
moving just a few feet in the horizontal distance can make more difference
than a large change in the vertical.

Source record: 151508

I am a Canadian Amateur who has been licensed since 1947 with an advanced class Canadian ticket and an Extra Class USA ticket. I work mostly CW and mostly on 40 metres.

The Canadian government has always given Canadian Amateurs a greater range of frequencies on which to operate voice than has the FCC to American Amateurs. It has often been referred to as a Canadian sub-band and is typically 50 kHz wide just below the bottom of the American phone bands. The original justification for that was that Canadians were not allowed to run as much power as Americans. In the immediate postwar years, Canadians were allowed only about 750 watts input power of carrier on both AM and CW. Americans were allowed a kilowatt. In those days, the American phone band on 75 metres was just wall-to-wall heterodynes with only a few readable signals in the melee. Canadian stations were not nearly as numerous (even on a proportional basis) and were able to operate with reasonable ease in their phone sub-band. In those days, I felt the arrangement was justified and reasonable. At that time 40 metres was entirely CW on both sides of the border.

Things have changed. For reasons I cannot understand, Canadians are still limited to less than 750 W of carrier output power on CW (which is the same as PEP on CW) but are permitted to run more than 2 kW PEP on sideband, provided they have an advanced license, which is easy to get now since only 5 wpm morse is required. But it goes farther than that. About ten years ago, Industry Canada (a catch-all government agency into which the Department of Communications was rolled several years ago) totally deregulated the Canadian Amateur spectrum. Canadians can now operate in any mode, anywhere and on any band. For example, a Canadian can operate 2 kW PEP sideband right in the middle of the CW DX window at the bottom of 40 metres, and do so legally. Fortunately, Canadian Amateurs have, almost overwhelmingly, chosen to continue to stick to the band plan that existed prior to the deregulation.

I can understand your frustration. I'm surprised that more Americans don't complain about it. It appears to me that the reason is pure politics. Canadians want more and the government gives it to them.

On the other side of the coin, the United States plays hardball with Canada in many ways that are not pretty. Most Americans don't hear about that.

Well, there are a heck of a lot of radio/tv stations that just keep on operating, right through heavy lightning - including direct strikes on the antennas.

It IS possible to isolate the radio equipment sufficiently that it is not damaged. It just isn't cheap to do, but a lot less expensive than replacing a $100,000 transmitter.

That's not the meaning of Amateur.
The amateur does something for the love of doing it, The professional does it because he wants the money. (Amateur is Latin roughly translated to doing something for the love of doing it). In many fields "some" Amateurs may be more knowledgeable than the professionals.

BS, they work just fine. The regs say you aren't supposed to use them while
airborn and the reason is that they tie ups so many sites, but they do work.
And work well in emergencies.

They certainly do, but it does depend on altitude. From 35,000 feet the signals and inside an airplane the signals "might" be a bit weak, but they normally do work, even if it is against the regs.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C36B814.1C94AC6@eznec.com>
Source record: 151517

NEC-4 is a program licensed by Lawrence Livermore National Laboratory. Its use is restricted to U.S. citizens and it can't be exported except under special circumstances with application through diplomatic channels. The price is $850, although I believe there is a discount price for universities. NEC-4 can't be downloaded from the Internet.

NEC4Win uses MININEC for its calculating engine. NEC-4 is able to model buried conductors, but MININEC (either the original public domain MININEC or the newer commercially sold MININEC Professional) and NEC-2 can't.

NEC-2 and NEC-2 based programs can accurately model horizontal wires within about 1/1000 wavelength of the ground -- but only above the ground. MININEC and MININEC based programs can accurately model antennas with horizontal wires only higher than about 0.2 wavelength. MININEC Professional can handle horizontal wires as low as about 0.1 wavelength.

In another posting I pointed out some differences between common antenna calculating codes. It seems that a lot of people think that NEC4Win is some form of NEC-4 because of its name. Here's some information about what the MININEC or NEC-2 "radial" feature really does.

In MININEC, the ground is considered to be perfect during calculation of currents and impedances. So no losses due to induced or conducted ground currents are ever included in the calculation. This is why MININEC can't accurately model low horizontal wires. If you model a very low dipole with MININEC, you'll get a very low feedpoint impedance (the same as you'd get for two out-of-phase dipoles in free space, spaced twice the distance as the above-ground dipole is above ground) and an incredible field strength. In reality, you see a moderate feedpoint impedance and a low field strength due to ground loss. NEC-2 models this accurately. In EZNEC, you can choose a "MININEC-type" ground model which assumes a perfect ground during impedance and current calculations, or a "High Accuracy" ground model which uses a realistic ground during these calculations, so by comparing the two it's easy to see the limitations of the MININEC approach.

After any of these programs calculates the impedances and currents, it then calculates the pattern. At this point, like the other programs, MININEC uses the ground characteristics you specify to find the strength and phase of the ray reflected from the ground to add to the direct ray to form the pattern. This gives you a realistic pattern shape. If you specify "radials" with MININEC or NEC-2, all it does is modify the conductivity of the ground for this reflection calculation. The antenna efficiency and feedpoint impedance don't change with the number of MININEC or NEC-2 "radials", since the "radials" aren't present during that part of the calculation -- they're used only for the ground reflection.

Surely the NEC4Win manual explains this important limitation.

In EZNEC, I found that users misunderstand what the built-in "radials" do, so years ago I disabled that feature. A user can enable it only by adding a line to the INI file (or for the older DOS versions, set an environment variable). This forces them to read the manual description of the limitations of the "radial" feature in order to find out how to enable it. Anyone having EZNEC 3.0, including the demo version, can find full information about NEC radials by looking in the manual index under "NEC Radial Model".

HI Frank

Thanks for the response.
I was hoping to make an untuned loop (because I will want to use it from 160 - 10) - so I was planning on feeding it with ladder line rather than coax so that I can tune it from the shack.

What's the effect of making the loop 'off square' (as in rectangular)?

It'll be simplest to feed it from the corner - does this have an effect ?

Regards
Adrian

StarGazer,
Are you SURE the trap is bad? I've had a R5 up for over 10 years and on several occasions thought I had trap problems. Turned out to be the antenna needed to be disassembled and cleaned where the tubes slide into each other. Just a thought. Good luck.

If you have connections for an external antenna on the back of your radio, you could place an antenna in the window, and run a line to your radio.

Of course, this may be impractical if the line would cross traffic areas, or if the window is in someone else's office!

But there are some pretty good external antennas you can buy at places that sell to the AM dx crowd, such as C.Crane & Co.

Other than that, I don't know of a way to receive a signal inside a metal office building.

> signals and inside an airplane the signals "might" be a bit weak, but they
> normally do work, even if it is against the regs.
>
Let us look at the link budget:

Assume 35,000 feet (6.6 mile or 10.6 km) in the air over a typical
metropolitan service area (MSA)
Assume worst case at 890 MHz cellular frequency
Assume 20 dB loss from inside to outside of typical airplane (about right
considering aperture size of window at 890 MHz)
Assume power out of cell phone is 1/4th watt or 24 dBm
Assume the cell site cable loss and the towertop preamp (TTA) and antenna
gain are unity.
Assume typical cell site receiver sensitivity of -119dBm to -123dBm (this is
typical for non-cryogenically cooled receivers)
Assume no Rayleigh fading because airplane is not obstructed.
Assume minimal Doppler shift because plane is under 770 mph.

Freespace path loss is: 32.44 + 20 LOG(frequency in MHz) + 20 LOG(distance
in kilometers)
32.44 + 20 LOG(890)
+ 20 LOG(10.6)
32.44 + 59
+ 20.5
111.94 dB loss through the air

The link budget is power output minus loss from interior minus freespace
path loss.
If the link budget power is greater than the sensitivity of the cell site
base receiver, the signal will be received.

So:

Link budget = +24dBm - 111.94dB - 20dB
= -107.44dBm

The cell phone has a margin of (119 - 107.44) 11.56dB to (123 - 107.44)
15.56dB.

The cell phone transmission will easily hit multiple cells.

I currenty have 4 dipoles center fed with 1/2 wave length of coax.(2 meters) At the ends of the coax there are series diodes switched with quadrature sine waves. In the older Doppler Systems units, a dual gate mosfet is used. One gate the control signal is applied, the other the antenna feed and a 50 ohm shunt resistor for matching. My question is, could one use a mosfet with a 3k shunt resistor on the end of a half wave element. This would simplify the mechancial construction and increase the gate impedance.

Only antenna worth trying (In my Experience), would be the largest even multiple of 40 meter full wave, horizontal loop, up as high as you can manage, fed with a tuner and open wire. I had a 528' horizontal loop on 40 that was a killer at low height, and worked 15 and 20 quite nicely. Wasn't interested in 80. Never tried an odd multiple, although might of worked even better. Best HF, non-beam antenna I ever had.

For sale...

Tri-Ex TM-358 Sky Needle tower. Includes 58' three section tubular tower,
newly recabled with SS cable, 10' thickwall mast, complete motor assembly
for controlled extension and retraction (120VAC), CDR sized rotator cage
assembly,
new hinged base, instruction manuals, a 1997 UBC stress analysis,
blueprints, and even the side mounted ladder!!!...the whole enchilada ready
to
grace your property.

Tower is down and next to my home. It is HEAVY (on the order of 1500#), so
it will take a wrecker or 15 very strong men to lift it out of the yard and
onto your car trailer. I will foot the bill to get the wrecker out to lift
it onto your trailer if that works better for you.
To install you will need to manufacture or purchase the re-bar assembly that
goes into
the hole (I have the specs and plans), gather up the gears and thrust
bearings for the rotator assembly (available through Tri-Ex),
and lots of labor!! This is not one of those lightweight and flimsy tubular
towers!

This is the cadillac of tubular towers. Very strong and rated at 12.4
square feet at 60mph, 7.2
square feet at 78mph, and 3.6 square feet at 95mph while fully extended!!
Dead weight capability is 400# including rotor and rotor cage.

Start your new year with a REAL tower that can actually handle realistic
antenna loads
yet still be asthetically pleasing to your neighbors.

Pictures available upon request. Email your questions or interest to
paul@dock.net

$2495.00 cash, cashiers check, postal money orders all OK.

Located in Thousand Oaks, CA (45 miles NW of LAX).

I'd go for a horizontal loop.. you should be able to fit at least one wavelength for 80 (260 feet or so). Resonates every wavelength, and is a champ on 40 and above with 50 ohm coax and/or a 1:1 balun. Get's a bit finickey above, but no problem with open wire and a tuner..

My Experience than anything that relies on the conductivity of the ground isn't worth messing with. I'd rather have a mile of wire in the air than a crappy 30 some foot pole in the air with miles of radials. Every Veritical I've ever tried on HF is a waste of time. I have had some success with vertical half wave dipoles, but much better luck with horizontal loops.

news:<VA.00003a1e.02c86222@dial.pipex.com>...
> What's the effect of making the loop 'off square' (as in rectangular)?

A not-good effect - it will start behaving less like a large loop &
more as a folded dipole hung too low. :-) I already made this
boo-boo. Since a true loop is circular, go for the most enclosed area
you can manage, and you'll have it OK. Obviously, the most enclosed
area you can have if there are only 4 sides, is a square. But it
doesn't have to be symmetrical either, so you could hang it as more
than 4 unequal sides, and it that gives more enclosed area (i.e., is
closer to a circle), so much the better.

> It'll be simplest to feed it from the corner - does this have an effect ?

That's fine & is what most do with horizontal large loops. If the
loop were vertical the feedpoint would matter more (polarization).

If the perimeter of a vertical or horizontal loop, triangular, square or circular, is somewhat shorter than 1/2-wavlength it can be resonated by connecting a tuning capacitor between the ends. Feed the loop opposite the capacitor with a balanced line.

Feedpoint impedance is low, generally less than resistive 20 ohms at resonance and gets very much less as the perimeter length decreases. It finishes as a magloop.

Download program MAGLOOP4 to estinate tuning capacitor values, etc. The program works as well on wire antennas as it does on copper pipes. Unfortunately thin-wire antennas themselves don't.

I was wondering about the real difference between those different
types. That kind of fills in the gaps. I guess I need to read the
manuals more.

I bet that it where they have improved in the past few years.

Who, for example, was performing the "research" you saw on
> TV?

Dunno, I'd have to go back and watch it again. I got the impression
they were in the south somewhere for some reason. Maybe FLA. But not
sure. They had a "shack" with all their instrumentation, and you could
look out a window to a "launch pad of sorts where they had the rockets
and leads, etc set up. Nearby was the house that they had set up as a
guinei pig. I'll check into it again and see if I can find out who
they were.

I know many researchers who will not allow entertainment media to
even
> observe normal scientific experiments because they never understand it and
> always mis-report it.

In this case, this was more like an "open house" where they demo'd
what they could do. They didn't show doing their "real" experiements.
They did show a couple or three rocket launches. One ot two which
resulted in strikes. I noticed one thing in their shack that
interested me quite a bit. They had a digi voltmeter on the wall that
they were measuring the voltage between ground and some elevated point
I'm guessing. They could watch that and get an idea when conditions
were ripe for a strike. I'd like to know how they rigged that up. I
want one here! They also had radar, weather info, etc, etc to know
when to get ready to test.

To restate the question, were the experiments being
> conducted by a committee or sub-committee of the standards writing branch of
> the National Fire Protection Association, or some other equally recognized
> standards writing organization?

I have no idea. But I would think there was some connection being as
they were doing tests on a "mock" house with appliances. Maybe they
mentioned it in the film. I'll get back to you if they did. I'll have
to dig it up and watch it again. MK

Thats interesting, prey tell me, where is 'tri-ex' these days? Last time I checked they are totally gone in the wind! (and don't tell me about WillBurt towers, their designs are 'not' the same as the original tri-ex stuff!) So that being said, how/where would one get 'anything' that would fit that tower?

The piece I saw was on the Weather channel, which (IMHO) is not your common intertainment TV. I think the work was being done by one of the Universities, and a part of it may have been in support of NASA. I know that NASA "Bleeds" off charges by firing rockets that trail wire into clouds, before launch. Otherwise the solid booster exhaust, which is high in acid ions, forms a path.

And that folks, is often where the posted question lies. How should I protect my $100 radio from the fury that may well burn my house down and kill me and my family.
A buddy of mine took a nice surge (I won't say hit) that zapped stuff all over the house. That clock radio probably jumped off the table at the moment of the strike and that moment of bell-ringing from the phones was short-lived and they dripped from the wall afterwards.
At the end of the day he wanted to blame it on ungrounded rotor cables. No, when the juice gets that close, the EEs are dousing water on their diplomas to save them. It will come thru power, phone, cable, grounds, etc.
One has to think in terms of preventing damage from mild-strikes, or even in static-buildup terms, because when the big momma comes to the typical ham-installation, average budget Joe Ham has few options apart from fire extinguishers.

Source record: 151452

First thanks to everyone who reply, both here and with direct email.

After a lot of testing, I was only able to get the swr to 2.0 and never more than a few khz of bandwidth. So, I left the loop in place for the moment as an open element. It is inside the 40m loop.

I finished the 40m addition to the 80m loop that already existed, put the balun's on this morning and went for a test drive.

I want to say that I am not an engineer, can't prove why the antennas are working the way they are, but here is the results from the analyzer and actual on air testing.

Here is the configuration: (the apex is 50 feet)

```
/\
/ \
/ /\ \ The 30m is inside the 40
/ / \ \
/ / \ \
/ --------x \
/---------------y
```

From the side the loops look like this:

```
| \
| \ \
| \ \ \
| \ \
| \
|
```

The 30m open loop is 30 feet back from the 40m and the 40 meter is 36 feet back from the 80m.

The loops are feed on the sides near the corners at x and y. Each loop is feed with 75 ohm cable as a balun to match the loops to 50 ohm. They are not cut to exact length but are very close, the 40m balun is 25 feet, the 80 balun is 50 feet. They are connected to a "TEE". The center of the tee runs to the shack and looks something like this:

```
50' to 80m 25' to 40m
----------------|======|-------------
||
|| 150' 50 ohm to shack
~~
```

Here are the results of the frequency test:

3.500 - 3.600 Swr 1.2 across range
7.000 - 7.300 Swr 1.2 across range
10.000-10.150 Swr 1.4 across range
14.000-14.350 Swr 1.4 across range
18.068-18.168 Swr 1.3 across range
21.000-21.450 Swr 1.4 across range
24.890-24.990 Swr 1.1 across range
28.000-29.140 Swr 1.0 across range

Here is the information from the analyzer: uh = microhenry pf =
picofarad

3.5 R=58 X=22 Xl=.912uh Xc=2242pf Coax Loss=7.0db
7.0 R=61 X=7 Xl=.167uh Xc=3086pf Coax Loss=9.1db
10.0 R=33 X=8 Xl=.133uh Xc=1673pf Coax Loss=6.5db
14.0 R=35 X=9 Xl=.103uh Xc=1247pf Coax Loss=6.3db
18.0 R=51 X=46 Xl=.407uh Xc=188pf Coax Loss=4.0db
21.0 R=39 X=22 Xl=.169uh Xc=338pf Coax Loss=5.6db
24.0 R=50 X=29 Xl=.187uh Xc=217pf Coax Loss=5.6db
28.0 R=57 X=12 Xl=.070uh Xc=454pf Coax Loss=8.7db

The coax is rg-59 and rg-8x

Now, my question: How is this possible with only two loops????

I used it on 12m and received dx reports ranging from 559 to 599.

30m was not open except for short haul communications, I worked a station in
Houston, about 400 miles south of me and got a 599+.

I worked a UT3 on 20m and received a 559.

Finally, I did one antenna comparison with a station on 10m in Reno, Nv. My
loops are pointed east/northeast, about half way between Europe and Africa
and would, I believe, for the most part favor Nv.

My 3 el yagi at 60ft was 2 db better than the delta loop at 50 feet.

The nice thing about the delta loop is that, like the yagi, I do not have to
use a tuner.....

Any explanations would be greatly appreciated, if not, it was an experiment,
killed a weekend and gave me something to do.

Again many thanks to everyone for your advice, suggestions and responses.

How can they tie up "so many sites"? By design, the cell phone will only associate with one cell at a time - although it will check the control channel signals from other cells to see if they would produce a better signal.

Most Amateurs don't even disconnect their coax outside the
building when a lightning storm approaches. Many don't even
have a ground connection on their equipment - except through
the AC outlet.

You might be amazed at what you could do with a few thousand
dollars. That is less than the cost of many recent top of the
line Ham rigs.

And that is the major point - your house and well being are worth far more than the radio equipment. You should spend the lightning suppression funds to protect the house and your life - without regards to the cost of the radio equipment.

> -Bill WX4A

A proper ground window and suppressor on the house mains will keep the strike from entering the house - or at least keep the damage minor. It won't matter whether the lightning strikes your antenna, the tower, the phone lines, the TV cable, a ground rod, or the ground somewhere close by. The hardest to suppress is a strike on the power lines - worst if it hits the feeder to your house.

"Average budget Joe Ham" probably spent over $1000 on his gear and if he has a tower and commercial antenna(s), several thousand dollars more there.

If he cannot afford decent suppression, as well as the gear, then he should buy a cheap rig and use a wire antenna without any tower or other expensive equipment. He could then spend the money where it is critical - protection of the house and occupants.

I never could understand it. A person will spend $20,000 - $40,000 every year or two to buy a new car - but they won't make a one time investment of a few thousand dollars that will minimize the chances of their house burning down.

No, it's mostly wind.

But neither is a solid sleeve of cast iron which would probably do better
than ferrite if it has a higher permeability.

But whatever is used it would be better to space out the individual sleeves
rather than bunch them all together over one relatively short length of
feedline.

378. Newbie DXing for Israeli broadcasts in UK.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-06 01:28:48 UTC
From: Z <post@imaZZZZris.demon.co.uk>
Message-ID: <sn7MZ$EQh6N8EwmQ@imaris.demon.co.uk>
Source record: 151463

Sorry I have sent this question to uk.radio.amateur also

I am DXing for Israeli Radio in the UK. I get internet but would prefer to recieve free to air broadcasts.
Kol Israel broadcasts daily on SW. What polarisation are the broadcasts?

Any radio rebroadcast transmitters of Radio Israel in UK? Is Kol Israel broadcast on digital or analogue satellite?

If there are other Israeli radio stations which broadcast internationally which I could DX I would be interested in knowing about them.

I'm not really a radio amateur I'm only looking to receive foreign stations and not to transmit. One of my SW radios (it is not even scanner class let alone amateur class) came with a wind up length of wire to set up as an aerial. This is obviously going to be of limited effectiveness so I want to install a better aerial. Seeing as I live in a block of flats though have a garden the aerial would have to be kind of inconspicuous and outside.

I know a little about Antennas and propagation for FM, UHF, and VHF but I'm not up on SW. I am a Telecomms Engineer, but I took the wireline path rather than the wireless path. What sort of cheap aerial could I start off with? For SW is it just going to be a whip, a folded dipole or something a bit more complex?

For DXing on UHF and VHF should I go with a Yagi Array and rotator? As I have to get an aerial erector to fix Ch1-4 TV aerial, fit a ch5 aerial and mix the two I may as well get all the aerials fitted by the aerial guy at the same time.

What is the highest tower I could fit without planning permission? It would probably vary with location I suppose. I would be getting something straight out of Andrews Corporation catalogue if there is something small enough.

As it's ages since I took RF courses any good sites to bring me back up to speed with Aerials.

Thanks.

Bill,
In theory, I agree with you. In practical circumstances,
I don't. To a large extent lightning protection depends on
where you live. If I lived in Florida, I'd certainly consider
it. In this particular part of Oklahoma where I live, lightning
just isn't ~that~ big a worry. I'm much more concerned about
wind than, lightning. Also, at least with the insurance
companies
I have had dealings with, having more lightning protection than
is normally encountered, means next to nothing (no 'breaks')
since
there are very few lightning related house fires locally. (I'm
not
counting those that are 'blamed' on lightning, only those that
are
~proven~ to be lightning related...big difference!)
So, the 'amount' of lightning protection that is practical
depends on circumstances, and all of us just don't need the
thousands
of dollars of protection that some others do...

I'm using a Comet GP-9 for my dual band base antenna. It's a little pricy at $170 from HRO, but it really works well. It was easy to put together, no tuning, and easy to install on a mast or tower stand-off.

Harold,

I've used several different types of glass mount antennas. Most of them will handle up to 50 watts, and worked reasonably well. One thing to consider when mounting the antenna is tinting in the windows. If your windows are tinted with a material containing metal, you will be in for some problems. I had a Larson glass mount antenna on my car that worked very well, but when I had the window tinted, it became virtually useless. I checked with the tinting installer and they told me that there was metal in the tint they used. Also, if you mount the antenna on the back window where there is usually heater wires, either mount the antenna between the wires, or if necessary, centered on one wire.

The down side to the Larson antenna that I had was that I had to trim the antenna to tune it. Not hard, but a little bit of a pain to unscrew it, use a hacksaw to cut it (I need better tools), and then re-check the SWR. The MFJ antennas have a tuning slug on the inside piece that makes tuning a snap, but I imagine the trade off is that a properly cut antenna will perform better than one that is tuned with a circuit.

Good luck,

Bob WA7VKF

Glenn Baxter, K1MAN, is sending this notification. I don't know what he is trying to prove save for wasting his breath. I mean, who cares??
.....
.....

Subject: Re: Broadcasting

AMERICAN AMATEUR RADIO ASSOCIATION (AARA)
INTERNATIONAL AMATEUR RADIO NETWORK (IARN)
K1MAN BULLETIN SERVICE
FULL INFORMATION AT www.K1MAN.com

"AARA is your alternative to ARRL. We sponsor IARN, which is the most experienced amateur radio emergency communications organization in the world."

This is Glenn's claim. He cannot verify it and Who Cares??

"K1MAN bulletins have been heard world wide since 1987. Like W1AW, K1MAN transmissions are perfectly legal under FCC rules. Like W1AW, good amateur practice requires publishing a transmitting schedule and then sticking to it. It is far more disruptive to do otherwise."

And maliciously and deliberately interfering with ongoing QSO's is not "disruptive"? Is not rude? Is not ILLEGAL? And Glenn has the anabashed nerve to mention "good amateur practice"?

"Hams can be very childish and territorial about the use of amateur radio spectrum. Our surveys show that about 1 ham in 10 is against both K1MAN and W1AW one way bulletins. We are sure there are also those who are against contests, nets, etc. This is OK! There is plenty of room for everyone in our Amateur Radio Service. If you have a problem with this, try another hobby; you are probably not cut out for big time Amateur Radio."

Yes, Glenn. You can be "very childish and territorial about the use of amateur radio spectrum." Your surveys are just that....YOURS! No need to use the plural "our", Glenn. MY survey shows that 6 of ten active Amateurs are against the K1MAN broadcasts/intentional interference and my survey is just as valid and likely more accurate than yours. The comment, "you are probably not cut out for big-time radio" is laughable. And what makes you, Glenn, think that you are "big-time radio"? Your silly ego aside, I have news for you. The only thing "big-time" about you is the constant pain-in-the-ass that you are.
Perhaps you should try another hobby. It is quite obvious that you are not

cut out for Amateur Radio and hopefully Riley will make that point painfully clear to you, sooner rather than later.

"An experienced ham knows that if you are trying to talk to another station per a sked, you might have to QSY one or more times during any given hour. If you don't know this and practice this, you are not am experienced Radio Amateur."

You are not talking to another station, Glenn. You are maliciously interfering with good Amateur operators and you do so several times daily. It is YOU who should practice QSY'ing. One must therefore surmise that you are, in your own words, "not an experienced Radio Amateur."

"Actually, our amateur spectrum is UNDERUTILIZED. The commercial guys are drooling over our spectrum and would love to divide us and conquer us. They love to see us squabble and act like babies. There are even evil persons in the FCC (dressed like good guys) who are very subtly promoting and documenting amateur radio disruption under a long term private plan to assist commercial interests take as much amateur spectrum as possible. A primary function of AARA is to warn you about this frequency grab and to expose the corruption that exists within the FCC. Corruption is nothing new in American politics, and if you don't think that our amateur radio spectrum is worth billions upon billions of dollars, you are very naive."

Here we have Glenn's agenda in a nutshell. He's a conspiracy theorist. He thinks Riley is a government agent in the pockets of Big Business. Glenn....ever look up the definition of "delusional"?

"So, join the fun. Listen to K1MAN on 14.275, 7.224, 3.975, and 3.890 MHz. daily and also call in (207 495 2215). See www.K1MAN.com 73!

14.275 MHz. USB and 3.975 LSB at 1:00 AM to 2:30 AM; 3:30 AM to 5:00 AM; 6:30 AM to 8:00 AM; 4:00 PM to 5:30 PM; and also 8:00 PM to 9:30 PM. 7.224 MHz. LSB at 3:30 AM to 5:00 AM. High fidelity amplitude modulation on 3.890 MHz. at 6:30 PM to 8:00 PM.

(All times are in Eastern Local Time - In winter add 5 hours for UTC) Join the fun! Get your unedited viewpoints on the air! 73 de K1MAN"

What "fun"? The real fun will begin when Riley comes knocking on your door! Go, Riley! Go!

384. Re: Antenna / SWR meters for 2m and higher

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-06 03:24:47 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C37C37F.A94247AF@eznec.com>
Source record: 151370

Tuners are usually used at the rig to match the rig to a non-50 ohm impedance seen at the input of the feedline. A common application is feeding a nonresonant antenna with low-loss ladder or open wire line, where the SWR on the line can be very high. At VHF and above, feedline loss is higher. When feedline loss is high, elevated SWR causes even more loss. So it's not usually wise to run a feedline with high SWR at VHF and above -- it's better to match the antenna to the feedline's characteristic impedance and keep the feedline SWR low. If you use 50 ohm feedline and it's matched at the antenna, no tuner is necessary. (Actually, I prefer this method even at HF, but there are lots of others that don't.)

Another reason is that while people want to cover multiple HF bands with a single antenna, this often isn't practical at VHF and above. The pattern of many antennas changes with frequency. HF users put up with this, but VHF operators often care which direction their antenna radiates, so can't tolerate radically different patterns on each band. There are some antenna types, like the discone and log periodic, that have a fairly constant pattern on different bands. But these also have a fairly constant impedance on different bands so can be fed with a low-SWR line without a tuner.

==========
1. There's not much need for them. Just construct VHF antennas and feedlines according to specified dimensions and away you go. Antenna tuners normally associated with SWR meters are not used at VHF. A more simple power meter is adequate to check that all systems go.

2. At VHF they are expensive to manufacture and calibrate with any degree of accuracy and cost too much to buy. Not much of a market for them.

Cellphone channel pairs are divided into 6 sets. Each site is assigned a specific set of channels (1/6 of the total available) and the frequency sets are duplicated in a hexagonal pattern. Then there are micro cells, but we won't go into that. The nearest cell will handshake with the airborne phone and carry the call, but the phone signal will be strong enough at all the co-channel sites to eliminate access to the one channel at each of the other sites. One of these isn't bad, but if everybody did it, it would tie up way too many assets.

I talked to a cel phone installer in our town. As you know, cel phone antennas are almost all glass mounts. I asked about the 3-M tint on my back window. He said they always use the inside mount as a template and cut the tint film away from the area where the antenna will be installed.

Even though the cell system is designed to only respond from one site at
a time, all sites that can hear the phone still are affected by the
signal. A device called a voter is used to determine which site will
handle the phone and all others are on standby if the signal strength
changes and another site is voted in and the old site is voted off.
It is a fact of radio propagation that the higher the antenna the
further the signal will go. If you are at 10,000 ft you might talk 100
miles but if you are at 20,000 ft you might talk 150 miles. At one site
per 2 to 10 miles you will hit a lot of sites and tie up a lot of
receivers.

Truer words have never been spoken. If you present yourself under
fraudulent pretense, the best you can hope for is (are) fraudulent
responses so the whole effort of disguising your email identity is an
exercise of a clown in a transparent changing booth.
There's little purpose in being a crocodile (all mouth and no ears) when
registering posts on Usenet., If what you have to say is relevant
there's no overcoming need to fear spam if you take even the novice
approaches of NOSPAM in your address. Simply shouting shit with your
ears plugged puts you into the category of yammering old cat-women
pushing shopping carts in the middle of a one-way street
Apart from the lack of adapting the same uzenet approach as the
grown-ups, one can only consider you as a kid who snuck into Mom's
bedroom to mess with the computer.
For that reason alone I'll not use my favorite bad words with you lest
there be some law in your area about mouth-whipping stupid pre-teens..

I wouldn't worry much about setting the trees afire, but you do want to be a bit careful about attic antenna installations, there is a chance of fire and an attic fire is not something you want to cause in your house. I know of a ham who set his attic on fire running 125 watts AM to an attic antenna. Make sure the antenna is well insulated, don't just lay it on rafters or pin it direcctly to them but use end insulators and keep it clear of all structural and metal objects. The high current point is at the center feedpoint on a halfwave dipole with the high voltage appearing at the ends. When arcing occurs, as can happen with haphazardly installed attic antennas in the characteristically dry, dusty atmosphere of an attic, you CAN have a fire result. Take care with your attic installations!

That's right, that decision was made LONG ago. And if US hams could use voice in the CW bands, you nor no one else outside the US would have a chance at all of being heard. It was done to protect the few (you) from the many (us). Leave it alone, nothing is to be gained from spreading the QRM across the whole band.

Yes, and no. Those of us who aren't ashamed of what
we post have no problem identifying ourselves. The rest
of us should go to newusers and read the netiquette FAQ.
If one does not understand the simple concepts stated there,
one should probably not be armed with a computer.

> Do so if you wish, but gird yourself for the dedicated

That's bull. I've been appending my crudely de-spammed
e-mail address and call sign to my USENET posts for over
ten years, and the little spam that I receive is the result of my
having a domain name (the address is different). It's funny
how anonymous cowards come up with all sorts of reasons
to justify their childish behaviors. Sorry, it just won't wash.

Almost all systems these days use antennas with downtilt
and really flat lobes. Just look at the published patterns.
Yes, one can hit the cell from an aircraft, but it isn't quite
as severe as some paint the situation because the sites are
rather deaf when one is above them.

I have done the same with good results, but many new cars
now come with glass that itself is very dark; there is now film
that can be removed. Why the automakers don't want people
don't want to see out of their cars is beyond me, but it appears
to be the current gangmemberwannabe fad thing...

Actually, it used to be 1/7th. That is no longer true, as there are not
enough frequencies to handle all the calls in densely populated areas.
So two adjacent sites may utilize the same frequencies. But the two sites
would beam their signals away from each other. This greatly increases the
available frequencies.

I am not convinced that the signal in the aircraft would eliminate access
by land based phones - as there would not be any handshake with that cell
from the aerial phone. But there could be a fair amount of interference.

If there were no voting, what you say is certainly true. But from my
understanding, as long as the signal between the handset and the cell
site is strong - there is no checking through the voting system to find
a better site. That would be a whole lot of unnecessary computation, as
well as a whole lot of unnecessary handoffs.

Agreed. I was talking about areas where lightning is a real risk.
Here in Western Oregon, the risk is even lower than in Oklahoma.

But I still have about $500 invested in minimal suppression equipment.
It is a one time cost.

OK, Mark. Call the shots the way you see them. If it makes you feel better
to call names, go for it. Maybe that is what it takes to make you feel
better about yourself....perhaps you feel a need to do this to bolster your
self-image.
I, in the meantime, will continue to carry on as I have done for so many
years now. Your input is inconsequential. Your name-calling is even less
relevant.
I hope you feel better about yourself in the morning.

>wants your antenna there isnt much out there that will save the antenna

I read somewhere that there is no need for a direct hit to get your
antennas or equipments get damaged. If there is heavy cloud - it will
contain lots of static electricity that may pass through your antenna
to your equipment!

The best protection is the lightening rod placed above the antenna
mast. It will direct the electricity to the earth or static
electricity down to earth. i have built up a wire -umbrella-
protection over my antennas and it works perfectly so far. I live in a
reion with lots of rain/lightening all the year!

I'm sure you'll delight in short-circuiting these greedy capitalists by
telling us the simple method you use. A simple example, with the size
and shape of the soil sample, the type of container you use, how the
analyzer is connected, the raw measurement results you got, and the
method you use to determine the actual soil conductivity and
permittivity from it, would yank the rug right out from under those
lowlifes by allowing any of us to make these simple measurements.
Personally, I'm looking forward to developing this ability. The first
thing I'll measure is a saline solution with easily calculated
characteristics, to confirm that the method is really reasonably
accurate as you say. I'm sure you've already done this, but it's always

helpful to have others verify your results when you're interested in making accurate objective measurements.

Thanks in advance for enlightening us!

Less than 1% of the spam I get daily comes to this address. (or any
of the variants) Most of it comes to my Yahoo address that I haven't
sent anything from in months.

>Should I use my call sign? Is that "macho"? Do so if you wish, but gird

My call sign is listed with my home address. Everything else goes to
a P.O. box. All of the 'personalized' junk mail (stuff to "Current
Occupant" and "Resident doesn't count, since they obviously haven't
looked anything up) ends up at the post office.

>
> Best regards, Richard Harrison, KB5WZI

No, this concerns all wires. Just because we bury them and call them radials doesn't magically eliminate coupling. The amount of coupling between wires in a V shaped orientation is of course different from wires which are parallel, so the values in Laport's appendix aren't correct for wires in a V orientation. But the coupling is there, and it's at least as strong.

Please re-read your earlier posting with its logical reasoning as to why radials don't couple. Apply that same reasoning to parallel wires fed in phase. Don't you conclude from that same reasoning that there's no coupling between the parallel wires? If so, do you suppose Laport (and all other authorities) are wrong in saying that there is coupling?

As I mentioned in my earlier posting, the current distribution is different for different numbers of radials. This is clearly shown in Fig. 42 of BLE's paper, and also shows up clearly in an NEC-4 analysis. If there were no coupling, the magnitude of the currents on the radials would be expected to change with the number of radials, but not the distribution (that is, the shape of the plot of current vs distance from the antenna). Yet the distribution does change, rather dramatically. This is due to coupling among the radials.

That's quite an elegant way of saying "no". Well done. But from you I
wouldn't expect less.

I guess we'll just have to keep struggling along as we have been, except
for those occasions when you'll give us the benefit of results you got
with your simple system. Oh, well. I was afraid of that.

The first part of their paper is a theoretical analysis of what happens.
It was shown later to be flawed (they also neglected coupling between
radials), but does clearly show that they knew the effect of ground
conductivity. There are even a series of graphs of theoretical radial
wire currents for four different ground conductivites.

Um, you have read or at least seen the paper, haven't you?

> . . .

You're confusing mutual inductance with coupled inductance, an error I seem to recall happening before. Mutual impedance (which usually contains a real as well as imaginary term) is a function of physical wire length, orientation, and spacing. Coupled impedance is the feedpoint impedance change that occurs as a result of mutual coupling. It depends not only on the mutual impedance but also on the relative magnitudes and phases of the currents flowing in the coupled conductors. You can find a good discussion of these concepts in Jasik or Johnson (in the chapter on medium frequency broadcast antennas), or a more abbreviated discussion in Chapter 8 of the ARRL Antenna book.

Mutual coupling among in any nearby conductors, including radial wires. The radials also couple quite strongly with the radiator. There's nothing magical about radial ground wires that exempts them from the laws of physics that dictate mutual coupling.

Perhaps where you live; here it is a iwannalookkewl thing.
Huge effect on safe driving on the freeway at night.
Sunglasses can be removed much more readily.

I had two identical cars, the second having been bought with tint.
Fortunately, the tint was easily removed (it was the stick-on type),
but horror stories abound about folks unpeeling their defroster
wires, so be careful with an uninstall. An on-glass antenna will
work okay if the offending material is removed from the area
where the two halves make contact (before installation, duh).

P.S. Thanks for the bar code info, that was nice!

Instead of answering me here (and worsening the signal
to noise ratio), you could have e-mailed me. I am sorry
to the others in this group that there are those who make
a mess of the USENET. This is like using a linked repeater
system (with many listeners) to talk to the guy just down the road.

> You stated, " I would have e-mailed you politely and privately"....

> e-mail address and call sign to my USENET posts for over

Well, goody for you, Petunia! The rest of us have had diametrically opposed experiences. I've been hanging around Usenet since it started, and never felt the need to disguise either my email address or my identity until the thundering hordes showed up on the Internet during the middle 90's. Just recently, I made an announcement via a moderated announce newsgroup and the spam immediately began (since it was a disposable email address generated JUST for the announcement, I know how the address was obtained by the spammers).

> ten years, and the little spam that I receive is the result of my
> having a domain name (the address is different). It's funny
> how anonymous cowards come up with all sorts of reasons
> to justify their childish behaviors. Sorry, it just won't wash.

Sorry, Petunia, your so-called "reasoning" doesn't wash either. The spamming is only part of it; the other part consists of stalkers.

Example: Two hams who have regularly posted to the rec.radio.amateur hierarchy in the past have harassed other posters by doing such things as calling their employers (even phoning Hawaii in one case), their neighbors, or their ISPs in an attempt at slander. One ham who still posts here under a pseudonym had to obtain a court order in an attempt to put a stop to the harassment. Another has had similar harassment by a non-ham, and is currently experiencing telephone calls and calls by "investigators" to his neighbors, again for the purpose of slander.

The standard response at this point is "take it to the police" or some such other nonsense, but the experienced harassee soon learns that there is actually very little relief to be obtained that way. I don't have

enough patience here to tell you about the failure of a court order to protect at least one ham from stalking. As with all things, an ounce of prevention is worth a pound of cure, and the best way to deal with the creeps who now hang out on Usenet is to never give them the opportunity to stalk you in the first place. The two people currently stalking hams IN THE REC.RADIO.AMATEUR HIERARCHY are both convicted felons.

Nice, eh?

> Mark Walsh ***** mark@die.spam.die.km6xu.com ***** http://www.km6xu.com
------------------------^^^^^^^^^^^^

Hahahahahaha! Continue to dream on, Petunia.

P.S. You need to learn the realities of true anonymous posting (which this is not). Any law enforcement agency can obtain my true identity by contacting my ISP with a subpoena. A truly anonymous post, such as those made through a mixmaster chain, cannot be traced.

The antenna structure isn't the only point of entry for lightning damage.
A properly grounded tower can also be the return path (through the
equipment) from a 'hit' on power or phone lines. Lightning protection
requires looking at the whole picture, not just one aspect.

I vaguely remember SGC saying that it will punch holes in the laws of
physics - it won't. It is a good antenna tuner but has lossess just
like any other tuner. It works with any source of RF over a certain
amount (5-10 watts?). What a remote tuner does is eliminate feedline
losses due to SWR > 1:1. For that purpose, it is excellent.

Running a ground wire won't work very well because it becomes part of your
radiating antenna system. What you need is a 1/4WL counterpoise for each band.

If you live in a southern state (Arizona, Texas, Louisiana, etc.)
glass tint helps to keep you from cooking like a lobster. Most states
have laws stating the maximum tint by window. Here in Arizona only
the rear and rear side windows can have the maximum tint allowed.
Both of our cars have the maximum allowed on all windows. I assure
you there is no negative effect regarding safe driving at night if you
are within the law. You really don't even notice the tint when you
are on the inside looking out. Sunglasses don't keep the sun off the
rest of your body.

Thats not very long. I went 20 years without a direct strike, and then had two direct strikes to my mast in the past three years or so. We also have mucho lightning here. "Houston". I didn't have any damage as I was grounded out. MK

440. Re: radials and vertical antennas

Roy Lewallen wrote:
"Please re-read your earlier posting with its logical reasoning as to why radials don`t couple."

Wires have mutual inductance. Close-spaced, parallel wires have a lot of mutual inductance. Radials are wires so they have mutual inductance. What does mutual inductance do? It either adds to or subtracts form a wire`s self-inductance. More inductance in a radial produces more impedance in a radial.

Inductance doesn`t allow current to change instantly, so more inductance in a radial means slower wave propagation. More inductance in a radial makes the radial appear longer.

Concerning symmetrical radial distributions, I said that voltages at the same point on adjacent radials are equal, thus no impetus should exist for current in the ground between radials.

Mutual impedance between radials may affect propagation velocity in them. If the radials are symmetrically arrayed, the radials may appear longer (I am repeating).

The more radials used, the closer they are together, and so the more coupling. Counter emf is of the same polarity as that imposed on an inductance so that current into the inductance is minimized. In a radial, self inductance and mutual inductance are additive and wave progress in the radials is retarded by mutual inductance (I am repeating again).

Mutual inductance between the radials in a ground system is small in its effect. Richard Clark opined that tighter coupling equalized behavior among radials.

The function of a set of buried radials is to produce a low impedance earth connection. Reactance in the earth connection can be tuned out as we tune the antenna system. What we want is low ground system loss.

There is an ARRL book, "Low-Band DXing" by ON4UN which includes much of what you might want to know about radials. Table 9-2 in that book gives the equivalent resistance of radials buried in good soil. Values range from 28.6-ohms for two radials of 0.15-wavelength to 0.1-ohm for 120 radials of 0.4-wavelength.

Best regards, Richard Harrison, KB5WZI

Yep. Two versions..A transister version, and a "deluxe" version using
the MAX232 chip. You could make a "psuedo" SM-20 mike from a rat shack
electret condensor element and save more big $$$. After looking at the
healthy prices they want for a simple cable for the faceplates, I'm
thinking of making one of those myself also if I can find some usable
end connectors. MK

If you are not hearing them with a 100 ft wire, sounds like the band
cdx are not very good. If there was a signal to receive, I would think
a 100 ft wire would do. Is noise a problem? I don't know what
distances you are talking or time of day. That will make a lot of
difference on 40m. MK

One of the most readable and correct for its time discussion of the cellular system appeared in one of the early Cheek Scanner Modification Books, of all places.

Now, Cecil, I want you to go back and look carefully at your question. Diagram=? Service power diagram? Yes. Site internal wiring diagram? Yes. Signal flow diagram? Yes. Logic diagram, yes I've seen one, but don't pretend to understand it, and most of the techs don't either. Were you attempting to ask something which ended up at cell radiation patterns? If so, those are available from the hardware manufacturers, and both Bogner and Kathrein published some really good papers in the 80s on those. Beam forming for PCS is much easier than cellular, but look around, you see both panel antennas and the old cylindrical type antennas in use at various sites, so there is no fixed answer. And few cell or PCS operations are run by "The Phone Company" anymore, even under a different disguise.

Yes, you could spend thousands of dollars and not make a difference, but
that assumes the money and effort were wasted on uproven techniques.

A properly installed grounding window does make a difference.

It may not provide total protection, but it will minimize what damage takes
place in the structure--in more instances that it wouldn't.

446. Wind Load Calculation

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-06 17:15:51 UTC
From: Drink <REMOVE_THISdrink@coqui.net>
Message-ID: <fy%Z7.144929$lV4.24934532@e420r-atl1.usenetserver.com>
Source record: 151333

I'm going to put up a simple doublet and want to have my technical facts prepared for when/if my local housing authority disapproves. I'm interested in calculating the wind load and other factors of an antenna. This could be a major factor in the event of a moderate hurricane.
Antenna is as follows:
30ft x 1 1/4" steel mast mounted vertically
450 Ohm (poly) ladder line feeder
14 ga. copper wire, mounted as an inverted V
Inv. V Apex at 30ft
Inv. V Ends at 10ft

I'm asking for you to *teach me how* to do it or direct me to a source vice fish for me. I may be as simple as a data table that accounts for diameter & length or as complicated as a basic formula. I appreciate any help I can get as well as additional info since this is a learning opportunity. TIA.

>
>I have a butternut HF5V-III antenna that the 75 Ohm matching section has
>been lost. If you know the length of this line please let me know. Thanks.
>WB7OYL
>
>
Have replaced mine twice with sections of RG-11 I had around the shack. It's a quarter wave long
on 20 Meters. You will need to pick a frequency for the calculation, I used 14.150MHz. Be sure
to allow for the velocity factor of the 75 Ohm coax you choose to use. May also I suggest that
you measure the VF and the electrical length of your matching section before putting it in line.
The published VF values were not consistent with the cable I actually cut. An MFJ-259B was used
for this work.

I also opted to put put a coax connector across the Butternut feed point so I could maximize
watertightness of the coax by using a PL-259 or N connector at the end of the matching section
instead of openning it up for direct connection to the vertical. That should add some life to
the matching section. My original matching section's center connector kept breaking. Repairs
allowed water to enter the coax, so I had to replace it, despite my best attempts to seal the
line against the elements. Hope this helps.

AMATEUR RADIO NEWSLINE(tm) REPORT #1273 - January 4 2004
(Total Running Time with RAIN Promo: 24:48)

==========

A NOTE TO THOSE WHO ONLY “READ” AMATEUR RADIO NEWSLINE(tm)

For those of you who only know of the Amateur Radio Newsline (tm) as a text newsletter we would like to invite you to listen to the audio version. This Amateur Radio Newsline (tm) script is actually written for the “spoken word.” It is recorded each by professional broadcasters and is available for private listening or rebroadcast over your repeater. Three methods of delivery are available: Streaming audio using RealAudio, FTP RealAudio, FTP MP3 or dial-in telephone. Please visit our website at http://www.arnewsline.org for a list of telephone numbers (you have to pay your own long distance charges) and links to audio servers providing our voice newscast. On site free FTP Downloads are available at our site by clicking on the newscast number at the top of the page.

de
The Newsline Production Team

==========

Amateur Radio Newsline report number 1273 with a release date of Friday, January 4 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T. A “V-E team” finds a way to test kids in one of the most remote regions of the country and the FCC again says no to expanding PRB-. These stories are first on Amateur Radio Newsline report number 1273 coming your way right now.

HAM RADIO TESTING REACHES WHITE MOUNTAIN ALASKA

Ham radio examinations have finally come to one of the remotest areas of the nation. This, after a team of examiners from the W5YI VEC perform a fly-in examination session in White Mountain Alaska. Amateur Radio Newsline’s Norm Seeley, KI7UP, has the details:

--

White Mountain is a remote fishing village in the far North-West of Alaska. It’s major claim to fame is that its the next to the last checkpoint for the famed Iditarod dog sled race. And it wanted someone to come in and give ham

radio exams.

The closest big city is Nome. White Mountain is only about sixty miles from Nome but its over some rather treacherous terrain. There are no roads in or out and all supplies to White Mountain have to be delivered by plane or boat.

But White Mountain does ham a ham radio operator for its mayor. He is reindeer farmer Tom Gray KL0CQ. And one of its school board members is Eric Morris KL7HT. Both will tell you that a temperature of minus 40 degrees Fahrenheit and a wind-chill factor of minus 100 degrees is not uncommon in winter. These were the conditions faced by a four member W5YI VEC test team when it chartered a plane and flew in on December 11th to administer exams to four adults and fourteen youngsters who were determined to make ham radio a part of their life.

The trip which cost $800 for the flight alone was sponsored by the Seward Peninsula Amateur Radio Club. Braving the weather were examiners Ramon Gandia AL7X, Michael Nurse KL7UJ, Scott Webber AL7RJ and Thomas Busch NL7H. Al four are from Nome. Most of those to be tested came from the Bearing Strait School District’s only inland school. They had all been studying for their Amateur license as part of a search and rescue course. Neither the applicant or the VE team were disappointed. All eighteen passed the Technician class exam.

For the Amateur Radio Newsline, I’m Norm Seeley, KI7UP.

--

Those involved in ham radio testing are keenly aware of the problems faced by remote areas of Alaska. At last July’s VEC Conference in Gettysburg Pennsylvania Jim Wiley KL7CC told the group that many applicants in Alaska are denied n Amateur Radio license exam due to the inaccessibility of their locations or the high cost of travel in that state. (W5YI)

**

HAM RADIO AND THE LAW: FCC SAYS NO ON PRB-1 EXPANSION REQUEST

Ham radio has lost yet another battle against deed restrictions, but the war is not over yet. At least that’s what the ARRL appears to be saying in a bulletin that describes the latest skirmish with the FCC over this politically volatile issue.

In the latest round, the FCC has affirmed a November 2000 staff-level decision that declined to include privately imposed deed covenants, conditions and restrictions under the limited federal preemption known as PRB-1. That’s the federal government policy requires municipalities to ''reasonably accommodate'' amateur communication in antenna-related zoning and regulation.

The ARRL last year appealed to have the full FCC review the earlier denial. The Commission turned down the League's Application for Review December 18 in a Memorandum Opinion and Order released December 26. As a result, it now looks as if the ARRL will bypass any further dealings on this issue with the FCC and will look for congressional relief instead.

The FCC itself even hinted that Congressional action by the ham community might be a next logical step. Its memorandum, opinion and order of dismissal did note that if Congress were to see fit to enact a statutory directive mandating the expansion of the FCC’s reasonable accommodation policy that the Commission would expeditiously act to fulfill its obligation there under. Translated: If Congress tells the FCC to include deed restrictions under the provisions of PRB-1, it will be more than happy to do so. (ARRL)

**

HAM RADIO IN SPACE: PROJECT JJ - HE EAGLE HAS LANDED

AMSAT-NA's newest satellite project, known as Project JJ for the past year, now has a new and official name. This, as AMSAT North America President Robin Haighton, VE3FRH, announces that effective January 1, 2002, the satellite will officially be known as 'Eagle'.

The name Eagle was submitted by Bill Allen, W7US, of Tucson, Arizona. It was selected from a list of forty-five names submitted by twenty-nine satellite operators.

For his winning suggestion, W7US will receive a free dinner at the annual AMSAT dinner held during the Dayton Hamvention. We will have more ham radio space related news later on in this weeks Amateur Radio Newsline report. (AMSAT-NA, ANS)

**

BREAK 1

Welcoming in the new year with ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, heard on bulletin stations around the world, including the N7VGS repeater serving the Salt River Star Valley Wyoming and congratulating 13 year old Devin Cassity, on becoming the youngest ham in South West Wyoming. Devin is now KD7PHN.

**

EMERGENCY PREPAREDNESS: NORTHERN CAL TOWN CHOOSES HAM RADIO

Ham radio started the year with some very positive public exposure in the Los Angeles Times. The January 1st edition featured an in depth article about a Northern California town that will tap into older technology to prepare for future emergencies.

Worried that a disaster will knock out e-mail and cell phones, Los Altos Hills has decided to turn to its local ham radio community and make it the primary back-up to normal disaster preparedness communications. And as you might expect, the hams are more than ready to oblige

The complete story can be read at the Los Angeles Times website. The complex URL is http://www.latimes.com/news/local/la-000000203jan01.story. (Highlighted by ARNewsline™)

**

AMERICA AT WAR: POPCOMM COLUMNISTS SAYS “DONT TURN THE OTHER CHEEK”

Popular Communications writer Eric Force has some strong words that are obviously aimed at the pacifists who oppose the United States military retaliation against Osuma bin Laden and his al-Quida terrorist network. As a response to those he calls the “do-gooders of the world” who promote turning the other cheek, Force says to look, really look at the attack that brought down New York City’s World Trade Center twin towers. He then says that it could have struck a lot closer to them.

Force says and we quote: “Consider that it could have been you, your mom, dad, brother, sister other relative or a close friend in those planes and buildings who were terrorized, murdered and buried in the rubble.” He adds that just thinking about the incomprehensible terror, suffering and losses incurred by innocent human beings a the cowardly hands of international thugs continues to tear at his heart.

Force has dedicated his latest I-Waves column to the sights and sounds of September 11th that are available on the Internet and to the victims of the tragedy. Its a very compelling article. You can find it starting on page 66 of the January edition of Popular Communications Magazine that’s on newsstands right now. (PopComm)

**

AMERICA AT WAR: FEDS TO AID NYC TV STATION REBUILD

New York television stations will be getting federal help rebuilding transmitters that were destroyed in the September 11th terrorist attack on the World Trade Center. A total of ten New York area stations will receive eight point two million to offset the thirty million to forty million dollar price tag for purchasing and
constructing a new transmission facility.

According to the Broadcasting and Cable newsletter, Senator Charles Schumer managed to secure the funding as addition to emergency aid appropriation for victims of the attacks. As previously reported, there is some speculation that the replacement transmitting facility could be a 1500 to 2000 foot high stand-alone tower constructed near the former site of the Twin Towers. (Broadcasting & Cable)

**

ENFORCEMENT: NAL CANCELED

The FCC has canceled a proposed ten thousand dollar fine that it had issued to Jeffrey Alan Pettrey, This, for his apparent violation of Section 301 of the Communications Act involving operation of an unlicensed radio transmitter.

Back on July 30, 2001, the District Director of the Commission's Columbia, Maryland Field Office issued a Notice of Apparent Liability for Forfeiture in the amount of $10,000 to Pettrey for the infraction. Pettrey filed a response to the N-A-L on August 7, 2001 accompanied by documentation regarding his

inability to pay the proposed fine. After reviewing Pettrey's response, the FCC conclude that cancellation of the proposed $10,000 forfeiture is warranted based on Pettrey’s inability to pay. (FCC)

**

ENFORCEMENT: FCC CANCELS CONVICTED HAMS LICENSE

The FCC has canceled the Amateur license of Kenneth P. Kelly, WT2FBI, of Greensboro North Carolina after Kelly failed to show up for a re-examination. But at the time of the FCC retest order Kelly was otherwise occupied. He was fighting criminal charges in relation to a jamming case in Ohio. We have this report:

--
On November 30, 2001, Kenneth Kelly, the ex-WT2FBI was sentenced to 5 years probation by the Judge H. J. Bressler in a Butler County Ohio court. He had previously been indicted on a 4 th degree felony charge of disrupting public service by his jamming and talking on the Middletown Ohio police radio system.

At his hearing, Kelly agreed to a plea bargain. He admitted his guilt to a reduced charge attempted disrupting public services. At the time the FCC pulled his ham radio ticket Kelly was being held in the Butler County Ohio Jail pending sentencing.

By way of background, a person later proven to be Kelly was first noticed on the Middletown police radio channel the third week of July 2001. Initially the police dispatch radio system was not recording him but that was soon remedied by city radio technicians. After several days of taping, it was observed that the voice on the police radio was similar to one heard on the local 2 meter Amateur frequencies.

Several members of the Dial Radio Club then assisted police by monitoring and taping Kelly on the 2 meter band. Tapes from 2 meters and from the police were then voice printed the aid of computers to check similarities. Dial club members also tried to direction find and locate the signal both on 2 meters and on the police channel.

Through some luck, detectives working with a metro housing police officer and discovered that Kelly was now living in their jurisdiction. After they interviewed him, they felt that he was the person interfering. As the investigation progressed, he admitted to detectives that he may have accidentally transmitted on their frequency by accident. He claimed that his signal may have been mixing with an FM broadcast station and another ham repeater.

But Police did not believe it was accidental, because he was taped trying to talk directly to the police dispatcher and the cars. Later Kelly did admit his guilt and entered into the plea bargain. Now sentence has been passed by both the local court and the FCC.

For the Amateur Radio Newsline, I’m Burt Hicks, WB6MQV, reporting.

--

When he was finally caught Kelly had a Yaesu VX-5 hand held in his possession that had been modified to transmit out of band. The assistance of the Dial Radio Club members is credited with helping to solve this case.

Note: Information and documents from the case can be obtained from the Butler County Ohio Clerk's office or online at: http://www.butlercountyclerk.org/ Click on Butler County Court Records Search. Then enter Kenneth Kelly. (FCC, Dial ARC, others)

**

ENFORCEMENT: MITNICK TO FIGHT TO KEEP HIS HAM LICENSE

Another ham who appears to be getting ready to do battle with the FCC is former computer hacker turned talk show host Kevin David Mitnick, N6NHG. Amateur Radio Newsline’s Bill Pasternak, WA6ITF has the latest:

--

As reported last week, the FCC is challenging Kevin David Mitnick's request to renew his ham radio license. The agency claims that his criminal background raises a substantial and material question of fact as to whether Mitnick possesses the requisite character qualifications to be and remain a commission licensee.

Now, N6NHG has told the U-K Newspaper the Register: "It's just another example of them trying to harass me. Now I've got to spend money to keep a ham license."

Mitnick insists that he has totally abandoned his former ways. The Register article notes that that he was recently called to testify before Congress on federal computer security matters. Also that he spent two days briefing the U-S Commission on National Security on these issues. Mitnick tells the Register that he cannot understand why the government is now questioning his character.

Mitnick is currently the host of the radio program called The Dark Side of the Internet. It airs in the Los Angeles area from 5 to 7 a.m. Sunday mornings over radio station KFI 640 AM. And in a recent appearance on Coast to Coast A-M hosted by Art Bell, W6OBB, Mitnick said that he is hoping for a career in computer security once his term of supervised release from prison has been completed.

For the Amateur Radio Newsline, I’m Bill Pasternak, WA6ITF.

--

The complete Register story and interview with Mitnick is on the web at a rather long and complex U-R-L. You will find it at http://www.theregister.co.uk/content/55/23494.html (Adapted from the Register)

**

INTERNET SECURITY: CIA GOES OUT OF ENCRYPTION COMPANY FUNDING

And speaking of Internet security, word that a Central Intelligence Agency funded company that allowed Web surfers to browse anonymously has closed. According to news reports, Emeryville California based SafeWeb enabled Internet users to gain access to the World Wide Web and browse sites through its encrypted service. This made their on-line habits and history untraceable. In the 2000 - 2001 fiscal year, SafeWeb received one million dollars in funding from the U-S Central Intelligence Agency's venture capital arm. (published reports)

**

HAM RADIO BUSINESS: AMATEUR RADIO TRADER CEASES PUBLICATION

Ham radio Internet auction sites may be responsible for a twice a month ham radio equipment sales magazine going away. This, after Amateur Radio Trader magazine announces that it has ceased publication.

According to Editor Barbara Patterson, KF4MMV, the Amateur Radio Trader was no longer a viable product. She says that the firm will be redirecting its resources into other areas.

Meantime, the company has also pulled its amateuradiotrader.com website off line. But unlike other publications which have gone under, in this case subscribers are being reimbursed for any outstanding issues. In addition to handling buy and sell ads, Amateur Radio Trader also donated page space to advertising the annual Newsline Young Ham of the Year award. (ARNewsline™)

**

HAM RADIO HERITAGE: MAKING WCC A PART OF THE FUTURE

A ham is campaigning to preserve part of radios past and have it become a part of the future. This as Lewis Masson, K1LJ-S, says that the town of Chatham Massachusetts should convert the site of radio station WCC into an Amateur Radio station along with a training curriculum to teach the kids in the area about communications technology.

WCC is one of the original Marconi Marine Radio Stations. Masson is an ex-marine telex operator at WCC. The site was recently turned over to the town of Chatham and Masson believes it is important to preserve the operations building as an operating amateur radio station and keep the hotel building as a museum to preserve and display memorabilia.

Masson says over the Internet that he has formed a committee to work on this project and that they are looking for nationwide support for this campaign. If preserving the past as an investment in the future is of interest to you, please contact K1LJS by e-mail to lemasson@juno.com. (Internet)

**

SPECIAL EVENTS: HAM RADIO UNIVERSITY 2002

A reminder the third annual Ham Radio University event takes place on January 20, 2002. Location is the Babylon Long Island New York Town Hall Annex with the doors opening at 9 a-m Eastern time.

Ham Radio University is a day of education about Amateur Radio. This there will be twenty, one-hour presentations with special forums geared to the non-ham as well as the experienced Amateur Radio operator. The focus will be "hands on" with many demonstrations. Besides the forums, there will be tables set up with information about the different groups, ham radio classes, exam session schedules, public service and other activities.

For more information about Ham Radio University, please contact its Chairman Phil Lewis N2MUN by e-mail to n2mun@optonline.net. You can also get in touch with ARRL New York and Long Island Section Manager, George Tranos N2GA by e-mail to n2ga@arrl.org. Also check the Ham Radio University website for a full list of forums, directions and talk-in information. Its in cyberspace at www.arrlhudson.org/nli/hru2002.htm (N2DO)

**

HAM RADIO RECORDS: BEST OF THE WEST AND VHF CONTEST HONOR ROLLS

Tim Marek, K7XC, says that he has updated W6 / W7 & "Best In The West" VHF Contest Honor Rolls. They are now available at the following web sites.

http://k7xc.tripod.com/VHF_Records/index.html s the stand alone records page. http://k7xc.tripod.com/K7XCweaksignal/ is where individual links can be found to each contest. (VHF Reflector)

**

HAM RADIO SCIENCE: NEW 6 METER PROPAGATION BEACON IN WASHINGTON STATE

Rich Ewing, KO7N reports over the VHF Reflector that Bruce Shurtz, W7BAS, has installed a propagation beacon in gridsquare CN87TG near Kennmore Washington. It operates on 50.069 MHz putting out 10 watts to a 5 element yagi pointing 90 degrees. The beacon is operational 24 hours a day, seven days a week. QSN reports go to W7BAS, at his callbook address. (VHF Reflector)

**

HAM RADIO IN SPACE: VERY FEW LAUNCHES

Peter Guezlow, DB2OS, reported that 2001 has turned out to be the slowest year for space launches in nearly 40 years. Ham radio or otherwise. According to DB2OS, only 58 flights reached orbit, and there was one complete failure.

Guezlow says that historians note that we must look back to 1963 to find a year that produced fewer launches. He says that in 2000 there were 82 launches to orbit plus three failures. By contrast the most productive year was 1984 when 129 launches delivered payloads into orbit.

But there is at least one bright note. Russia successfully placed five satellites into orbit recently after launching them aboard a Zenit rocket. The cargo rocket, carrying three Russian, one Moroccan and one Pakistani satellite, took off from the Baikonur space center in Kazakhstan. (AMSAT, ANS)

**

HAM RADIO IN SPACE: NEW INDIA WEBSITE

The AMSAT-India website has been officially launched recently by the government of India and the Department of Space. VU2POP says that you can check it out by taking your browser over to www.amsatindia.org. (ANS)

**

CONTESTS: HUNTING LIONS ON THE AIR

The 31st annual Hunting Lions in the Air contest will take place on the weekend January 12th to the 13th. The contest period will be 48 hours and will run from midnight UTC Friday night to midnight UTC Sunday night, and all hams are welcome to participate.

According to its sponsors, the objective of this operating event is to create and foster a spirit of international understanding and cooperation among radio amateurs and members of the Lions Clubs through the use of world-wide radio communication. The contest also commemorates the birthday of Melvin Jones, the founder of the Association of Lions Clubs who was born at Ft. Thomas, Arizona on January 13, 1879. (Q-News)

**

DX

In DX, word that the recently postponed Ducie Island Dxpedition is on again for March. Ducie Island became a DXCC entity last November and it immediately jumped to the top of the most wanted contact list. But rough seas scuttle the first attempt to put it on the air. (RSGB)

Meantime 6 meters continues to be the V-H-F D-X band of choice. On Monday December 31st, Kevin Bishop WB8XX, says that he started hearing O-H-1-X-T at 1300 U-T-C on a backscatter path. From then on until 1620 U-T-C he worked 8 new countries and over thirty new grids in Europe and Asia. (VHF Reflector)

**

STRANGE TECHNOLOGY: ARE CELLPHONES KILLING GHOSTS?

Now, from radio communications to the effect of radio communications on supernatural communications. This, as a British expert who has spent years researching the occult says that cellular and other mobile phones are killing off ghosts. Don Wilbanks KC5MFA has the details:

--

No, we are not kidding you. In fact, Tony Cornell, of the Society for Psychical Research, has told the London Sunday Express that reports of ghost

sightings started to decline when mobile phones were introduced 15 years ago.

According to Cornell, ghost sightings had remained consistent for centuries. In fact, until three years ago the society received one or two new ghost sighting reports every week. But with the introduction of mobile phones 15 years ago, ghost sightings began to decline to the point where they are not receiving any.

And why are there no longer any ghosts being observed? Apparently paranormal events, which many scientists attribute to unusual electrical activity, my be drowned out by the electronic noise produced by cellular telephones and text messaging pager transmitters. And according to the newspaper, the lack of ghost sightings could adversely impact on the nations economy. It says that haunted tourist attractions in Britain could be under threat if the number of cellphones continues to grow from the present figure of about 39 million now in use in the U-K.

Don Wilbanks, KC5MFA.

--

And all of this begs that one question be asked. If ghosts are the spirits of the dead, how can anything actually kill them? (Science Today)

I'm just up I45 in Madisonville. What I have done is use banana plugs/
sockets at the plexiglas "firewall". I unplug the banana plugs and
tie the ladder-line to the hurricane fence when lightening threatens.
Even if I forget, wind almost always occurs before the lightening
and the ladder-line unplugs itself. I've been doing that for
14 years and suffered no ligntening damage.

451. Entangled Photon Pairs

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-06 19:26:47 UTC
From: CAM <Cecil.A.Moore@IEEE.org>
Message-ID: <3C38A4F7.DEA5A792@IEEE.org>
Source record: 151338

The Dec. 8 copy of "Science News" has an article titled "Gadgets from the Quantum Spookhouse". One thing it describes is "entangled photon pairs". I think we hams should get back to the leading edge of communications by putting up a satellite based on these entangled photon pairs. In geosynchronous orbit, we could beam one photon beam at the East Coast and the other at the West Coast and have instantaneous full-duplex communications between the coasts.

452. Re: Looking for SG-239 Smartuner feedback, pros and cons

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-06 19:49:45 UTC
From: Anthony Duffy <a.duffy@sympatico.ca>
Message-ID: <3C38AA59.4090601@sympatico.ca>
Source record: 151339

From what I understand of this "antenna coupler", is that it's a self adjusting network installed at the base of the antenna. It works with the elements connected to the terminals the same way adjusting a tuning network at the base of the antenna does. The handy thing is that it's automatic, actually tunes the elements to resonance instead of faking the radio into thinking it has a good SWR (ie; antenna tuner at the radio), and can be used on any radio with a minimum of a 3 watt output (for this model). It can also be used with allot of different styles of antenna including a multi or single turn loop.

It's going to be my next acquisition too.

As for the down side, any antenna that is reduced in size and compensated for using coils and caps will be less efficient (some more then others). But not as bad as using traps from what I've read (and the antenna is still quite large). Oh, and it does have minimum radiator lengths depending on what band your going to be using it on.

If you'd like a better idea on how it works go to SGC World. There is a link to their publications where they have downloadable manuals and also one on using their products with stealth antennas. It was an interesting read.

I wouldn't let the premiums lapse. Not unplugging the antennas and grounding outside will get you one day. You never want to invite that stuff in the house with you. If the coax is the "best" return to ground for the strike, from the lack of a good ground at the mast, it could burn your house down. Not to mention fry everything in the shack. I'm talking dime sized holes blasted though cases, welded together , etc, etc. May take 20 years to happen, but it will sooner or later. Having a ground wire to the rig means nothing as far as lightning protection. In some cases, it can eat your lunch. I've seen it happen more than once. The "ground" needs to be outside at the antenna/mast. The least resistance to ground at that point, the less problems you will have. I've taken two direct hits on my mast in the past 3 years, but I didn't have any damage at all. Why? All my antennas were grounded out outside and my mast is well grounded and directs the strike to ground fairly efficiently. All grounds are tied together also. I also unplug the phone line and any uneeded gear from the 117v lines. But it's probably not really needed, as I haven't had any damage to any plugged in electrical gear and the breaker box and lead-in is 5 ft from the mast that takes the strike. I would be more likely to get that type of damage from a power line strike than a hit on my mast. I was sitting at this computer when one of the strikes hit, and the computer which is plugged in, didn't flinch at all. Not even a blip. BTW, good lightning protection doesn't have to cost 1000's. 500$ probably would cover it. Probably less if you are handy. It's well worth it if you don't want to unplug before every storm. Also, you might forget someday. It could happen to me. Sometimes storms will roll in so fast I barely have time to unhook. There has been more than one time when I was pulling cables while lightning was striking in the area. Scary ass @#$% let me tell you. A strike while I'm holding those cables , and I'll be dead before I hit the floor most likely. At the least, I'll wake up a good while later with problems that will last years or maybe the rest of my life. Most that get struck regret it. Only certain type forest rangers like the one struck 8 or 9 times seem to get a kick out of it. And I bet if you asked him, he'd say he could have done without them. :(MK

Roy Lewallen wrote:
"You`re confusing mutual inductance with coupled inductance----."

Mutual inductance couples individual circuits which may have no physical connection. This occurrence is called inductive coupling and the circuits are said to be inductively coupled. Transformers exploit mutual inductance to transfer energy from one circuit to another without requiring direct conductance between the circuits. This is called transformer action, that is, current in one circuit results from voltage applied to another through the magnetic flux linking the circuits. Transformers can couple reactance and resistance. Readers of this thread probably know how this works.

Parallel wires behave as transformers. They just have less self inductance and less mutual inductance.

In the analysis of transformer action, the secondary impedance may be transferred to the primary. The total primary impedance is the sum of the actual primary impedance (Zp) and (omega M) squared / Zs. The term "(omega M) squared / Zs" is called the coupled impedance. This can be in part or in total a coupled inductance, if that is what is loading a secondary.

Best regards, Richard Harrison, KB5WZI

Peter Bertini wrote:
"Yeah, but you won`t know it is not working until you have a nearby hit."

Lightning protection works on radio installations that can`t be disconnected in stormy weather.

When is the cab dispatcher busyiest? During the sudden thunderstorm.

When do listeners pay attention to the radio? When they are hunting storm information.

How about TV and cell phones? Are they fair weather facilities?

Radio dispatched facilities of all sorts tend to be busyiest in stormy weather. The electric power company, the telecom company, police and fire, etc. These guys are busy in bad weather.

Most professionals don`t disconnect the radio and throw the coax out the window when a storm approaches. They can`t. Hams don`t need to disconnect everything either because adequate protection can be affordable. Most protection comes from cable routing and grounding.

I`ve worked with countless fixed radio installations and very few had lightning problems. Those that did were solved.

The guys who scare hell out of people to sell them expensive protection gadgets they don`t need should be ashamed of themselves, but they`re chuckling at how many chumps there are out there.

Best regards, Richard Harrison, KB5WZI

> How is the antenna analyzer connected to the bucket?
==========
Want to know a secret ? You'll never guess. Alligator clips.

I have on occasion measured the resistance between Europe and North America using a long test lead formed from coaxial cable, inner conductor a bundle of high-tensile steel wires with anti-torsional lays, clad longitudinally with an overlapping annealed copper tape, surrounded by an extrusion of purest polyethylene to a diameter of 0.99 inches at 20 degrees C. Outer conductor = six slowly spiralling pure aluminium tapes. Then a thick outer jacket of more plastic. A real precision engineering job which didn't let in water like RG-58 even at depths of 2 or 3 miles.

It always struck me when making such measurements how very incongruous it was to have to make connection to the extreme end of 2000 miles of such beautiful stuff using a few feet of 22-gauge insulated wire salvaged from the station junk bin, terminated with an alligator clip from Woolworths.

Aaaah, such sweet memories of the 1950's. And of days aboard oceanic cable laying ships with nothing to do but show the radio operator how to make a crystal set and connect it to the ship's antenna. Many years later I visited a ship-to-shore radio station to take my 12 wpm morse test. Lo and behold the morse testing officer was the very same fellow as had been aboard the cable layer. I passed first time.

I'd at least spend 20-30 bucks for a lightning arrestor of some type
if I didn't unhook during storms. Even a cheapy model. And hook it to
a good ground rod. Won't really protect the radio much, but it should
keep from burning the house down. This is per code. Applies to TV's
also. All tv and radio instruction manuals recommend a lightning
arrester for outside antennas. MK

Not all 2M 5/8W whips will work on 6M. Some use series coil matching
on 2M, and those will load up nicely on 6M. You might want to add
a 1" or 2" extension with a piece of copper wire at the tip to get
the swr down.

I have an old Antenna Specialists model that I use this-a-way.

Then there is the series capacitor-tapped-to-a-coil style of
2M 5/8W whips. These will *not* work worth a hoot on 6M.

This example of household damage is not necessarily the energy of lightning. Lightning can strike the 13 Kv line, create a plasma short through a transformer, then leave with little damage. But the plasma short remains, pumping 13Kv directly into a residence. That 13K is called follow through current. Lightning typically is not a high energy transient. The power utility can provide the destructive energy. It is why that ground wire to a utility pole transformer is so important to your surge protection system.

Stray cars have a habit of cutting that ground wire. Since many don't understand the importance of earthing, then that broken ground wire is too often ignored. After all, lights still work so that wire must not be important. As noted too often in this thread, earthing is the heart of effective surge protection. Surge damage is too often directly traceable to a human who did not understand that surge protection is only as effective as an earth ground system. Instead, others use the 'woe is me' defense and claim one cannot install effective lightning protection. It is simply a question of spending just a little to protect from 90% of the strikes, more to protect from 98% of the strikes, or big bucks to protect from 99.999%.

Lightning strikes typically occur about once every eight years (tends to vary according to geology and geography). Therefore six months is like saying I did not catch a cold in the past two hours, therefore I will never catch a cold.

Actually there are good reasons for this. My van is tinted and I wanted it to be. First it cuts down on the heating in the summer sun. Two it cuts down on folks glaring into the car at the family while we are on the road (specifically in parking lots). Three it cuts down on folks looking in the window for what goodies might be found within the vehicle. The ONLY down side in my mind is that it puts policemen at ill-ease if they pull you over.

I'm duly impressed with your measurement of the resistance between our continents. And now, armed with the detailed information about your method of measuring the conductivity of your back yard soil, we can make our own measurements.

As soon as I read the connection method you use -- silly me for not having figured it out on my own -- I made some measurements using your method. I found that when I fill the metal bucket with dirt and attach the antenna analyzer to it with alligator clips as you suggest, I get the same reading no matter what I fill the bucket with. Using your method, all grounds have the same conductivity as a bucket of bullshit. Remarkable! As always, you've managed to make a complicated process very simple. Thanks!

478. Re: Antenna / SWR meters for 2m and higher

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-07 00:51:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C38F10A.77C5052B@eznec.com>
Source record: 151366

Nearly all modern commercial transmitters, especially ones designed for VHF/UHF operation, are able to operate without damage into nearly any sort of load. If the mismatch is too extreme, they'll reduce output power to protect themselves. HTs, in particular, are often used with very poorly matched antennas, and are seldom damaged because of it. If you want to get the best from your antenna, feed it with 50 ohm line. Put an SWR meter in line and adjust the match at the antenna (by adjusting the element lengths or stub length, and tap points) for a 1:1 SWR. The SWR meter can be either at the antenna or at the rig during this adjustment. Having a low SWR will assure the lowest possible line loss and the full power output from your transmitter. (Working to lower the SWR below the point at which the rig will deliver full output isn't worthwhile if the line loss is reasonably low.) The SWR will normally be lower at the rig end of the feedline due to feedline loss, but with a J pole or ground plane you can expect some variation in SWR (and pattern) with feedline length and orientation. This is because the feedline couples to the antenna and becomes part of the radiating system.

Hardline is coax; it's just a little bigger and stiffer than what most
of us use.

If I remember correctly (it's been more than 30 years) only part of
the tower was actually driven. There was a grounded base, so the
hardline had to go part way up to the actual tie point.

Dear Roy,

How you love to unnecessarily complicate matters !

KIS. ;o)

Anyone wishing to get the feel of how shallow-buried radial systems behave quantitatively, versus number, length and frequency, can download programs RADIOETH, EARTHRES & ENDFEED. They've been available for several years, free to USA citizens plus a money-back guarantee.

I shall not divulge the source code because inevitably it would be subjected to very ill-informed criticism from people afflicted by delusions of accuracy and some of the mud-slinging would stick.

But, of current interest, I can confirm the source code in no way gets bogged-down with red herrings such as the mutual impedance between radial wires. That source of interference to an analysis can be removed by considering the radial system to be a continuous flat sheet with conductivity intermediate between copper and the soil. But it's just not worth all the trouble.

The only acceptable criticism should be based on measurements made on actual radial systems, qualified with realistic measurement uncertainties including the uncertainty of soil properties. So don't forget to measure them.

Roy, you will agree this approach to validation of mathematical modelling formulae conforms exactly with your own measurements philosophy.

The only claims I make are that accuracy is adequate for the intended purpose and results are available within seconds. A two-weeks training course on data entry is unnecessary.

I bet that's put the cat amongst the pidgeons! ;o)

Hi Dave,

Which transmitter? We had about 60 HF transmitters there, almost 40
were 10KW and the rest were 40KW. The antenna farm was spread out over
three square miles. I remember one grass fire that spread through the
farm and over part of the ammo depot up the valley. It burned almost
2000 acres and never got close to the fences.

Let's see, The destroyer I was on was home ported in Pearl Harbor. I
was on it from August '70 till April '74. It got back from my second
visit to Vietnam in March '73, a few weeks after the cease fire. I was

transferred to Lualualei in April '74, worked there 22 months, and then moved to the TTY repair shop at Pearl Harbor. I was there until my discharge in April '77. We left Hawaii in February '78.

I think the VLF output was classified back then, but yes, it was 1MW somewhere between 15 and 20KHz. It put out an FSK signal at 50 bits per second.

Thanks for questioning Jerry, last communications I had with whomever it was that took over Tri-Ex, it was specifically stated that it was no problem getting the rebar cage, but that they recommended just getting it locally as you'd save the freight costs as the cage weights quite a bit. As for the gears required, information is in the provided packet and you can get those from any gear speciality shop as they aren't anything special. But at least everyone knows what to expect now.

It does not need anything specific to the to tower, just a generic rebar cage made to print (which I have) and a pair of gears for the rotor cage (as well as the thrust bearing for the mast). Hardly a difficult project to any ham who's been around the hobby for a couple of years.

Message-ID: <RW8_7.798$B36.613727@news20.bellglobal.com>
Source record: 151279

I'd like to hear from anyone currently using the Outbacker Stealth Plus antenna mobile. Just undecided whether to go with the Yaesu ATAS-100 or the Stealth Plus. They are both about the same price up here in Canada. I like the in-car tuneability of the Yaesu, but like the compactness of the Stealth. I've read the reviews on eham.net and looking for a little more info from guys using them. If you are using the ATAS-100 I'd also like to hear from you.

If you aren't using either antenna, please don't waste your time replying. I am not into mounting a 7 or 8 foot tall screwdriver on my car.

Thanks to those who do reply,

ve3tmt@rac.ca - please respond direct, tnx

493. Just a comment on losses in the ground.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-07 04:31:31 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a1b8n4$pk23b$1@ID-124126.news.dfncis.de>
Source record: 151281

It is popularly understood that an increase in soil resistivity always results in increased losses in the ground such as the ground in the vicinity of a vertical antenna.

But this cannot be true because when soil resistivity increases to the point when it can be considered to be an insulator the ground loss becomes very small again. Soil permittivity causes radiation to be reflected or refracted with little loss back towards to the sky.

So there must be some value of soil resistivity at which ground loss is at its maximum. What is it ? Is that the value in YOUR back yard? Should you consider moving house?

Reg

That's the beauty of entangled photon pairs. Once they leave the transmitter,
the quantum communication between the two particles is actually
instantaneous, i.e. there is no delay between the changes (modulation)
in the two particles, i.e. faster than light communications is possible.
If I twist a photon in Los Angeles, the twin entangled photon in New York
undergoes an opposite twist. The satellite delay is irrelevant. In fact,
there is no up link at all - just a transmitter.

I'd like an antenna (either fixed or telescoping) with a swivel at the base (so as to make it possible for me to adjust it to a right angle) and terminating in a male F connector. This is to be used on an Onkyo home receiver for FM reception. Is this possible? Anyone make such an animal? Even if you think it may not work well, I'd be interested in trying one to see what kind of results I can get.

Thanks,
Phil

499. Pryme RD-98: heavy or light?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-07 05:30:12 UTC
From: senecal@mapson.cs.ucdavis.edu
Message-ID: <senecal-0601022130120001@d71-096.solano1.ucdavis.edu>
Source record: 151287

Hi all,

I'm considering a Pryme RD-98 for my VX-5R. Can anyone tell my how heavy (or light) the antenna is? I've installed a Yaesu SMA-BNC converter, and I'm worried about the antenna making the radio top heavy and stressing the connector.

Thanks!

-Josh Senecal

>Suffolk UK

If you can cut a magnetic loop (fed continuous loop) to be resonant
on a ham band, it will be resonant at higher odd multiples of that
frequency. With this in mind, coax will not be a problem. The nice
thing about using coax is you don't have to worry about proximity to
surrounding objects. You can make an adapter to use at the shack end
that shorts center to shield to feed it on frequencies lower than the
design freq , and feed it against ground (if you have a very good
station ground, and a respectable vertical run of coax of respectable
hight out side) as a capacitive top loaded vertical.
If you're encountering high SWR at certain places due to not being
able to cut it to full size, naturally ladder line will be to your
advantage.
It doesnt matter where you feed the loop, but most folks feed it at a
corner for obvious reasons.
The shape of the loop doesn't matter, but it performs best when the
loop encompasses the MAXIMUM area inside the loop (perfect circle).
Remember, more wire means more danger from lightning or other simple
causes of static. Dust, precipitation, wind, all of these can cause
extremely high amounts of static electricity to build up on a wire, so
it's best to have the whole thing shorted to ground when not in use...
preferably pulling the feedline outside of the shack to do so.

Good luck, cu on the bands.
Mike/N4ZN

Cecil, an excellent first step. Thanks for putting us on the right track.
Did BL&E have anything to say about this non-trivial matter ?

Consider the CFA above deep, perfectly dry Sahara sand. Conductivity
measured in micro-siemens. Would a horizontal 1/2-wave dipole laid on the
sand surface perform better? It would certainly be less expensive! Who's
for a shoot-out expedition to Timbuctu ?

Yes, that is what I was questioning. Should I earth ground the mount.
Then from what I am getting I need to run a counterpoise connected to
the mount for each band I want to operate.

Why is it that people seem to discount wire antennas right off the bat? For $5 you can put up an effective, even if not efficient, multiband antenna that is extremely stealthy.

If the ground wire from the mount to ground is 1/4WL, it
will adversely affect the feedpoint impedance. It's like
connecting one of your 1/4WL radials to your transceiver
chassis. I got literally burned by such a configuration
about 50 years ago.

It is virtually impossible to get a solid ground 30 ft up in the air.
The "ground" wire can carry standing waves, can adversely affect the
feedpoint impedance, and can result in lots of RF-in-the-shack. IMO,
go with the counterpoise for each band and wrap a few turns of coax
to achieve some choking action. BTW, you will be running QRP on 80m.

It seems to me that ground reflections would be pretty poor using
deep, perfectly dry Sahara sand. I don't think dry sand can compete
with salt water. Speaking of which, do any hams live on the shores
of the Great Salt Lake in Utah?

Ok so this is what I am going to do---
My roof is 20' high asphalt shingle almost flat. I am going to mount the antenna on the roof without using an earth ground attached to the mounting bracket. However attached to the mounting plate I will attach a 1/4WL counterpoise for each band I will be using (I have a triple resonator mount). I will lay the counterpoises horizontally on the roof extending out from the mounting bracket. I will make a choke at the the base of the antenna to help keep RF out of the shack. Sounds like a plan. By the way I considered a wire antenna but believe it or not I don't have the room except for maybe a 10M dipole. Also considered a verticle but don't want to mount a 20' verticle on the roof of my home. Live in a duplex and the neighbor won't go for it. Can't ground mount it "cause there is no room on the ground for radials.
Thanks for all the suggestions. I will keep watching posts.
Ron

It looks as if the first attempt will be something like 100m total -
just due to the way the land is arranged - and where suitable supports can be
placed. The feeder will have to stretch out at maybe 30 degrees from horizontal -
the field where the loop will be is up the slope from the bungalow / shack.

> You can make an adapter to use at the shack end

See above - also not sure how good a ground we'll be able to achieve - natural
'soil' round here is very sandy - and drains water away very quickly....
I may be able to locate the rainwater 'soakaway' - so 'planting' and earth rod
'under' that might be a good start..

Yes - that's a good plan. Might even be able to arrange some sort of 'remote
relay' shorting arrangement up where the loop is - keep some of the HV away from
the shack.....

Hopefully it'll be a good location for HF & VHF - we're at 15m ASL - but more or less at the top of a hill (we don't get very big hills round here <g>). The North Sea is about a mile away .... and I've got a generally good take-off in all directions.....

Cecil, W5DXP wrote:
"It seems to me that ground reflections would be pretty poor using deep, perfectly dry Sahara sand."

Terman assumes 3.5 degrees to be the minimum practical angle above the horizon for rays departing a shortwave antenna. That makes maximum skip distance roughly 1000 miles to 2000 miles depending on the sky reflecting layer and its height. To reach farther requires more hops.

To use 3.5 degrees means you may need an earth reflection point about 2000 feet from your antenna in the 160-meter band. How good is the soil at your reflection point? How smooth is the earth surface there? Surface irregularities can be worse for a reflection than high soil impedance.

Best regards, Richard Harrison, KB5WZI

They are on the Art Bell website (http://www.artbell.com) but that has been turned into a pay-site for accessing the audio. It was an older program but was replayed during the late summer of '01 as one of the 'classics' while Bell was on vacation or sick...along with ones like the guy who was arrested for stealing power company transformers for the construction of his Time Machine. :-)

Since they went 'pay' with the site I understand that the old show archives are pretty extensive but for that same reason I haven't been back.

Send an email to k1man's aol account and see what happens. You wind up on his unmonitored mailing list that then starts spewing his crap back at you. If you ask to be removed, then THAT message gets you on the list another time, and so on, and so on.

THAT is why my email address never shows up in newsgroups - some people figure they have the liberty to do whatever they please with no regard to the other person's wishes. Same thing as with my phone number, it's up to me to decide who can have it.

And, yes, AOL has been notified and requested to take "appropriate action" to the k1man account.

Astro',
Theres absolutely nothing you can do to clear up the
'garble',
it's built in to all K1MAN's broadcasts. If you want to increase
your knowledge of ham radio, and contribute something to the
hobby,
the best thing you can do is not listen to K1MAN.

Cecil,
I have no idea of how the guy's home is constructed. But,
I'd be willing to bet that the length of the ground wire would
be less than a 1/4 wave on 80 meters (+/- 62 feet). For 10 and
15 meters, a 1/4 wave would be about 8 and 11 feet respectively.
I would also hazard a bet that a ground from the mount to earth
on these two bands would be even multiple of a 1/4 wave. Any of
which should work fine for the three bands. But (another one),
since he's already decided to use the counterpoise, this is all
beside the point...

Adrian,
I wouldn't be too concerned about the aspect ratio (l/w)
until it really got out of hand. A 3/1 aspect ratio, two
sides being 3 times as long as the other two sides will have
some affect on the radiation pattern, but not much. Same for
the input impedance (which you wouldn't care about anyway).
The idea is to get as much area inside the loop as possible.

I ran a similar antenna with counterpoise, and found the counterpoise had to be adjusted very precisely for each frequency, so plan on some finagelling of wire length. Also, the counterpoise will be hot with rf energy -- you may want to consider insulated wire to keep from heating the shingles. Otherwise, should work fine.

> >some of the hissing/crackling????

I used to add an external antenna to my Sears Silvertone transistor radio back in the early 60's by coupling an external coil to the internal loopstick antenna. It used to pull in some pretty distant stations.

Here's what I did. First, figure out where the loopstick antenna is. If it's internal, you will probably need to open the case to find it. The loopstick will be a grey bar a few inches long, with fine wire coiled around it. Using #24 magnet wire, wind a few dozen turns around the exposed end of the loop-stick, bringing the wires out through the case. Alternatively, you may be able to just wind a coil in free air and tape it to the outside of the case, just off the end of the loopstick (with your windings on a plane parallel to those built onto the loopstick). I seem to recall doing it both ways.

Now connect a long wire to one of the coil leads (the longer the better) and a ground to the other coil lead. The ground can be a connection to the central screw on a power outlet (caution! Electrical system MUST be grounded properly!), or a copper water pipe, or just another long wire run along the floorboards. Try your reception now.

Another approach I have read about (but not tried) is the "magic wall", where you wind a large (6' diam) coil with the ends connected into a closed loop, and affix it on or in a nearby wall. Any radio brought into its field gets better reception, supposedly. I've seen this written up in Popular Electronics of decades past. No clue if it really works.

Andy Markham wrote:
How long do I make the RG 58 so the length is ideal?"

Using your numbers, the velocity is less in the cable you propose to substitute, so less length is required for the ideal phase shift.

Multiply 86 ft. times the ratio of the velocities which is 66/78. The length Andy needs of RG-58 is 72.77 ft.

And since you are going to all that trouble, I would also
suggest TWO 1/4WL counterpoises per band, laid out 180 degrees
apart. That will *tend* to keep the counterpoises from radiating
and tend to turn the counterpoises into ground planes.

And if that doesn't work, add 118 more radials. :-)

The typical conductivity around here in East Texas is supposed to be
4 mS/m. Where I was in Arizona is supposed to be 8 mS/m. I don't know
much about this subject. Which is lossier? Salt water is about 5000 mS/m
and free space is zero mS/m. Salt water is lossier than free space but
we know salt water is closer to ideal for HF than is free space.

Thanks for this......

I'll just have to do some 'empirical performance testing' -
also known as 'suck it & see' <g>

Perhaps we'll start out square - maybe with a conventional long
wire for comparison - and see how they compare.....

Thanks again
Adrian

Cecil, W5DXP wrote:
"Which is lossier (4 mS/m or 8 mS/m)?"

Well, I think a mS/m is a millisiemens per meter. The millisiemens has the same conductance as 1000 ohms. The siemens is a new name for the mho which is the reciprocal of the ohm.

The FCC`s Ground Wave Propagation Curves show less r-f loss for more ground conductivity in all cases. So, 4 mS/m is lossier than 8 mS/m. The 4 mS/m earth is less conductive.

Salt water is lossier than free space because free space is closer to a perfect insulator than salt water is to a perfect conductor. Salt water is closer to ideal as a reflector for h-f than is free space which doesn`t reflect at all.

Best regards, Richard Harrison, KB5WZI

Source record: 151193

According to the RAC web site (our version of ARRL) the 40m band in
Canada is as follows: (from http://www.rac.ca/hfband.htm)

40 Meter Band - Maximum bandwidth 6 kHz
7.000 to 7.035 MHz - CW
7.035 to 7.050 MHz - Digital Modes
7.040 to 7.050 MHz - International packet
7.050 to 7.100 MHz - SSB
7.100 to 7.120 MHz - Packet within Region 2
7.120 to 7.150 MHz - CW
7.150 to 7.300 MHz - SSB and other wide band modes

We can work voice from 7.05 to 7.100 so we are able to QSO VE - G. I
looked on the ARRL web site for the US band plan but it didn't specify
any segments of 40m as CW or SSB. Only those that weren't.
(7.040 RTTY DX, 7.080-7.100 RTTY, 7.171 SSTV, 7.290 AM calling frequency)

Guess we'll have to just do it the gentlemanly way for now until both
the ARRL and RAC get it synchronized. Is there a problem with the use of
the band or just the way it's explained by the ARRL?

Just my 2 cents

One first has to create a radio frequency photon. A half wave sine
pulse of one electron charge will do in a pinch. Next we need an
infinitely high Q nonlinear downconverting antenna, identical at each
end. Super conducting rare earth metal q= 10^9. Well have to wait 40
years until we can get a room temperature superconducting carbon
nanotube nanotaylored antenna. Then we need a way to direct the photon
to each receiver, humm...

First of all, let me say that I have a VX-5R, and I think it's a great radio. If you get one I think you'll be pleased with it, but take my opinion for what it's worth! :) The rubber duck that comes with the radio isn't bad, but like all stock ducks it isn't the best, either. I'm also in the process of looking for a new antenna (I posted about it recently). I wanted one that would give me all three bands too, but there aren't that many. Most antennas are for 2m/70cm.

Things to might want to consider: are you going to install an SMA-BNC adapter on your radio (A BNC connector is a lot less of a hassle than SMA)? If you get an SMA-BNC connector you might want to look into a non-Yaesu connector. I have the Yaesu one, and I think they could have done better. Make sure that the antanna you purchase will not make the radio top heavy. This can stress (and break) your connector.

As far as antennas I'm probably going to get a Pryme RD-98 dual-bander. The only antennas that I've seen that offer 6m/2m/70cm are the Maldol AH510R and the Diamond SRH999. The Maldol comes SMA or BNC, but the Diamond is only SMA. I have never used either of these antennas, so I can't offer any opinions on them, although if the Maldol is light enough I'll probably get it instead of the RD-98, since I really want the 6m capability.

Good luck!

-Josh Senecal, KG6IBF

Actually, I just checked AES and I found both of the antennas you mention, as well as the Maldol MH510 and the MFJ-1720S, both SMA antennas. The MFJ was the only one I could find specs on ($30!). As far as the radio, I've done a bit of research and found that this is the radio to get... it's as cheap as a dualbander ($255 from AES or HRO), but you get 6m as well!

You might be mistaking the RD-98 (which IS available in SMA for you!)
with the Pryme AL-800 metal telescoping unit.

The RD98SMA or RD98BNC is very light - and not anywhere near the
"mass" of the AL-800 or other solid antennas. It is an excellent
performer for your HT!

> some of the hissing/crackling????

Something you could try that costs nothing is to place the radio very
close to something that is run off the 117v line. Such as a lamp, etc.
Many times the power lines are fairly hot with local RF and you might
be able to get a decent signal near your desk. Walk around the room
and place the radio close to anything plugged in and find a good spot.
I'm sure you will see an increase of some type near power lines. This
could work for FM or AM. Never know until you try it. MK

"Unquote." is improper here - as did not quote.

If you remove cargo from a ship, you are lightening the ship.

The first definition has to do with removing a weight or burden.

569. 21~50 MHz Quad EZNEC Model

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-08 10:20:20 UTC
From: post_to_usenet@hotmail.com
Message-ID: <b6b4e772.0201080220.37ab31a@posting.google.com>
Source record: 151207

Hi,

Playing with EZNEC I have got to a Quad design that should not be possible: good gain, good bandwidth, low SWR, many bands. I know this is considered not possible, so it probably has some failure that I cannot see (I have no formal studies on antennas nor much experience with modeling them). I have seen that when used with too long segments, EZNEC tends to be over optimistic on antenna gain. Maybe the catch is this, that with the proper number of segments gain would be much lower (and/or SWR higher).

This antenna would work all ham bands from 50MHz down to 21MHz. SWR < 1.7 for 50 MHz, < 1.8 for full 21 MHz band and < 1:5 on all frequencies between 23.5 and 34 MHz. Feed would be by 300 ohms parallel line. Catch: It requires 120 mm (~ 4in.) cable diameter, so some kind of wire cage is imperative.

Please comment if this design could possibly work, and what is wrong if not.

Thanks for answers.

Toni

I do not know if the .EZ file will get posted; if not copy and paste the following wire definition to a text file and import it in EZNEC. In addition, wires 2, 3, 4 and 5 have a 33pF capacitor (no coil) at 50% position. Source is at 50% on wire 1. Alt Z is 300ohm.

```
----8<----8<---- cut here ----8<----8<----

> And the feedline length is *that* critical?

I know what you mean. The aerial is, like I say a Carolina Windom 80 Beam.
It works on all bands and must have a ATU (Transmatch).

The manufacture states that the optimum length of feed line is 86'. I think
this will give a internal ATU of a rig the best chance of coping with the
SWR, otherwise you have to use a external ATU as well.

Must be that the feed line is part of a wavelength or something ?. As my
feed run was already close to 86' I just thought I would give it a try.

Andy

Interesting.. anyone ever adapt those auto electrically retractable antennas for this? Probably work just fine if you decouple the motor wiring from the elements. 30" of varable length on each element end of that 80 meter 3 element yagi would do wonders.

I would be prepared to explain that the mast is being installed in accordance with manufacturer's recommendations. Example : I have four Radio Shack 35 ft push-up masts set in concrete and guyed with 3 guys at two levels and one at the top level. These masts support a 480 ft horizontal loop. The wind loading in your case is very small compared to the basic structural integrety of the mast and guys. I used augur type ground anchors (swing set variety) in a 12 inch deep hole filled with concrete.

If you are a member of the ARRL they may be able to help with a source for wind loading information. I considered the info in an old publication when I put up my tower and beams. Simple wire antennas have a negilible wind load.

I'm just curious: is it correct to assume that the current AM broadcast band is really the best choice of frequency for the desired characteristics for that service? In other words, was 540-1600 kHz (before expansion to 'AM wide' a few years ago) chosen first, and then the stations placed there? Or did the stations begin operation in that frequency band and just happened to choose a good ground wave frequency band for local broadcasting?

I've been reading some of the history of KDKA, which of course was the first commercial broadcast station in Pittsburgh in 1920 (on 360 meters, according to the original FCC license), and it seems that the Westinghouse engineers knew that starting around 1500 kHz ground losses increased, making those frequencies less useful for local reception. (They apparently didn't know about sky wave propagation). But aside from that, is there anything magical about the current broadcast band that makes it the best choice?

Thanks,

Al W6LX

Mark Hall wrote:
"---ANY worthwhile attribute of a ground counterpoised vertical for HF?"

Medium wave broadcasters early in the development of their business found greater efficiency in the vertical radiator, combined with a good ground system, than other antenna systems gave.

If you want to launch waves parallel with the surface of the earth, the vertical is for you. If you want to launch waves at only small angles with the surface of the earth, say 5 degrees or 10 degrees, as may be useful for long distance sky wave propagation, the vertical may be for you. Good earth conductivity and an efficient ground connection are needed with a 1/4-wave vertical.

A horizontal antenna over sea water at heights under 1/2-wavelength does poorly.

Two figures in the 19th edition of the ARRL Antenna Book compare horizontal and vertical 1/2-wave antennas better than words can. See Fig 4A and 4B on page 3-5.

Mark Keith says: Experiment!
Reg Edwards says: Alligator clips!
They have something!

About 40 years ago Japan was exporting crystal sets called rocket radios because they were made to look like toy rockets. They were permeability tuned. The knob was the rocket`s satellite payload. They had a high-impedance crystal earphone that pluged into the ear and an alligator clip lead or leads for making aerial or earth connections. The whole thing was smaller than most cigars and worked very well.

To me, the surprising thing was where a usable signal could be found with those alligator clips. Experimentation may yield similar surprises within the questioner`s building.

Indeed they do. I've been using them for 60 years or more. They were invented before sliced bread.

On this side of the pond we refer to them as 'crocodile' clips.

Crocodiles inhabit the Nile. I understand alligators inhabit the swamps of Florida.

I have noticed when clipping on the turns of PA tank coils, in a strong RF magnetic field, it ie easy to get thumb and forefinger burnt if the clip's base material is steel. So if there's a choice prefer the brass variety because they run cooler in that application.

You won't find THAT advice in ARRL books, Always glad to be of practical help.

Source record: 151217

Hello Philip,

I just did a google search on "java gis open source" and it found many pages of hits.

I noticed OpenMap on the first page of hits.

I think the JCS contract should use something like OpenMap as its UI. We would have to add the readers and writers specified in the contract to OpenMap. The alternative is to spend time building a custom UI that only supports the mapping functions required to satisfy the JCS contract. If we don't graft JCS/JTS onto an existing GIS UI, we would still have to build something that would handle map display, zooming, and editing.

OpenMap has a rich set of reading, querying, display, and map saving functions. It would be a good start. Some of the other open source packages may be a better start.

Cheers, Greg

MF broadcasters use vertical antennas for two reasons only - they radiate most strongly along the horizontal, ie., a strong groundwave, and they are omnidirectional.

This was known long before BL&E.

It so happens only one mast is needed and it is sound economics to use the mast as the radiator instead of using it just to hold up the wire.

True. Early broadcasters often used a T antenna. The horizontal section was a capacitive load ffor the vertical wire. As Reg noted, only one tower was used to replace two needed to suspend the T antenna, when the switch to the base insulated radiator was made.

BL&E answered the question as to how best make the earth connection for the vertical antenna.

The problem is not completely defined. You have to know what the
grounded side of the unbalanced antenna feedline connects to. If it
goes to a stake driven into the soil, then low resistivity (high
conductivity) is good; if it goes to a ground "plane" made of highly
conductive radials, then the popular understanding that "an increase
in soil resistivity always results in increased losses" is incorrect.
The problem also ignores the dielectric constant of the soil which, if
very large, negates losses associated with soil resistivity.
With the introduction of parameters for these other variables, a peak
(or valley) in a plot of efficiency vs. ground conductivity could
probably be found for a given antenna and grounding (plane or stake)
geometry, but you'd probably miss several payments on your mortgage
trying to figure it out and have to move anyway.

For a given antenna, there is always a soil conductivity/resistivity at
whixh ground losses are at a maximum.

Just as there is always a load resistance in which maximum power is
generated when connected to a given generator.

Might his page have changed? I found no such conclusion nor
comparison thereon, but rather a good comparison with centerfed dipole
performance. Likewise, his captioned article covering the inverted L
did not mention the large loop, and basically concluded that the L is
a good alternative for limited space. Kindly clarify "convince."

596. New Old Stock- Hy-Gain 18HTB Hy-Tower For Sale $400.00

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-08 22:35:55 UTC

I have a NEW never installed Hy-Gain 18 HTB 10-80 Meter Hy-Tower that has the Manual, original box (slightly tattered), all parts and a Stainless Steel Hardware kit in addition to the original hardware. The tower sections are still banded together. Base insulators are there too, it's complete! The only catch is I don't want to ship it, so please don't ask, it's a pickup only. I am 30 miles north of NYC, Pomona, NY. I may deliver it for expenses locally (30 miles) if you can't pick it up. It will go on a roof rack or in a van or pickup.
Hy-Gain is selling them now for $739.00
$400.00 gets it.

I would have to disagree with the concept of any so-called "tuner" or coupler actually tuning
the radiating elements to resonance. The only way to do that, unless I am just dead wrong, is
to physically lengthen or shorten the whip, dipole, or long wire to do that. While I don't mean
to put down tuner/couplers, nothing beats a resonant antenna. I still believe the various HI Q
HF antennas such as Bugcatchers and screwdrivers will stomp a coupler. Again, they do work
by reducing SWR, but they still exhibit losses, and you STILL have a non-resonant radiating
element out there

I have to agree with there on having a resonant antenna is best, but in limited space etc they can help out the same as inserting an L-Network at the base of some antenna designs does. Even the screwdriver antenna uses a very large coil to tune an 8' whip antenna that would resonate on 10m down to 80m. These outfits just happen to switch coils and caps in and out to do the same thing. And as a bonus that are automatic to boot :-) !

Jerry, a non-resonant antenna will radiate just as well as a resonant one.
A non resonant 102 ft dipole fed with ladder-line on 40m is essentially
just as efficient a radiator as a resonant 40m dipole fed with coax.

K7JEB runs a Texas Bugcatcher mobile with an SGC-230 tuner used for
broadbanding. The difference between the performance at resonance
and the performance off resonance is measurable but essentially
negligible.

One advantage that the very large screwdriver coil has is that it radiates.
The iron core toroidal coils in the SGC don't radiate much. Another factor
is that a screwdriver antenna is center-loaded while an SGC driven antenna
is base loaded. I measured an SGC driven whip in a 75m mobile shootout.
It was 14 dB down from a Bugcatcher plus top hat. Virtually all of the
RF power was soaked up by the SGC.

You would be better off buying a cheap yagi...

> Should this folded dipole be erected vertically, or horizontally?

It should match the polarization of the transmitting antenna.
The http://www.fcc.gov database lists the polization for all
of the licensed stations in the USA, so check there. Most
of them use circular polarlization, so trial and error is your
best bet there. Most pirates use verticals. Check out
alt.radio.pirate for more details.

> band for local broadcasting?

I think the latter is closer to the explanation. Actually in the
earliest days it wasn't a 'band' in that context. 360 meters was the
norm for nearly ALL broadcast stations in June 1922 for instance. By
the following year they began spreading out but even still only a scant
few dared go above 1300 kc.

All the while in the early 20s there was an ongoing battle between
amateurs (many of which evolved into broadcasters) and commercial
stations. Hamming for ham-sake scuttled off above 200 meters as their
operating became a pest for broadcast listeners.
Here is an excellent page from an excellent site detailing the creation
of the broadcast band.

That's interesting... I thought the screwdriver antenna was base loaded,
or at least it looks like it. The SG coupler suggests using the whip
antenna on 40m and up and 23' of wire for 80m and up as a minimum. The
manual for the LDG version mentions that it was designed to be used to
take an antenna and resonate it 1 band above and below it's design, i.e.
a 40m antenna for use on 80m & 20m. For Wire antennas and ladder line
fed antennas there is a 4:1 balun available.

Hello Bill,
Happy 4 el Quad owner here. I've had a stack of a 105ba and 115ba at 70 feet. I then replaced them with a 4 element Cubex. One obvious advantage that comes to mind (me personally) I needed to lower the overall windloading. So, 3 bands with monoband performance on one boom was a winner. My antenna was up for 4 years and I lost 2 wire elements predictably because they were alluminum wire. Now at a new Qth and a new installation with coperweld 14 awg wire, I'm convinced it will stay up for quite a while. Durring hurricane Opal, I got some cool photos of the yagis' elements culing back like blown grass. The quad I have witnessed barely moved durring some of the fiercest March thunderstorms to rip through Georgia. There is a slight difference in recieve noice to sig. However, this is the most powerful antenna I have never had to enhance with the use of an amplifier... nuf said. Try finding someone who has one and put your ears to it. I'd be happy to let you try mine :)
cheers,
de Mike

Yes Dino, thanks. The 259B board is very different and bears little relationship to the 259. Darn it! I thought your article would take care of it all, but no such

luck. I've hung on to your article though -- I spend a lot of time servicing stuff for
the local ham community and I've learned to hang on to good information just in case!
Thanks again.

I use a three ft optional extension on the bottom of mine. Thus, the
center loading. In any case, the sleeve that covers the coil is part
of the bottom radiating section below the coil.

> The SG coupler suggests using the whip
> antenna on 40m and up and 23' of wire for 80m and up as a minimum.

Seems if it is 23' minimum on 80m, it would be 11.5' minimum on 40m.
An SGC-230 plus a 11.5' whip would be a little over one S-unit down
from a screwdriver on 40m.

Oscillator technology was a limiting factor in the early 1920s.
There is a great book called, "200 Meters and Down"
(available from the ARRL and elsewhere) that is a good
read with lots of interesting history. Check it out!

Reg wrote:
"For a given antenna, there is always a soil conductivity / resistivity at which ground losses are at a maximum.

Just as there is always a load resistance in which maximum power is generated when connected to a given generator."

That seems to be an affirmation of the maximum power transfer theorem.

The antenna is not the source to be matched by the ground system. A transmitter feeds a resistance which is the total of the radiation resistance and loss resistances. The antenna is 100% efficient if there is no loss. The antenna is 0% efficient if the radiation resistance is zero.

Say, we have an antenna with a radiation resistance of 28.6 ohms. Say, the antenna element and its matching network are lossless.

Our ground system won`t be lossless. Let`s use ON4UN`s Table 9-2 in "Low-Band DXing". For 2 radials of 0.15-wavelength, the equivalent resistance to ground is 28.6 ohms. For 120 radials of 0.4-wavelength, the equivalent resistance is equivalent to 0.1 ohm.

Say, the transmitter can deliver its maximum power of 100 watts into 50 ohms, and we have a tuner to make our antenna load appear as 50 ohms to the transmitter.

The tuner delivers 100 watts to a series combination of two resistors, the radiation resistance of 28.6 ohms and the radials` equivalent resistance, which depends on their number and length.

With ON4UN`s 120 radials of 0.4-wavelength, we only add 0.1 ohm to the 28.6 ohm radiation resistance of the antenna when we add the ground system to the total. When 100 watts feeds this system, less than 1/2 watt is lost in the ground system. Nearly all of the 100 watts is radiated.

With ON4UN`s 2 radials of 0.15-wavelength, we add 28.6 ohms to the 28.6 ohm radiation resistance of the antenna and 50%, 50 watts, is lost in the ground system. Of course, that`s only 3db or half an "S"-unit.

Best regards, Richard Harrison, KB5WZI

619. Re: Quad vs. Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-09 05:41:58 UTC
From: vswrref@hotmail.com
Message-ID: <3c3bd455.21220899@national-news.stargate.net>
Source record: 151255

Hi all.

I'd have to throw in my 2 cents, it's not about the performance between yagis and quads, it's about how amazed I am to see how many people fail to correctly point a yagi so that there is minimal windload. I know sometimes this may be hard to do, timewise, if a storm is fast approaching. When I can tell which direction the winds are coming, or storm is approaching, point the element ends into the the direction of the approaching winds. Windload on the boom is minimal compared to 3, or more elements, on it all facing the the wind. I had 4 storms blow through my location, in 23 years, with 80 to 85 MPH clocked at the local airport, about 3 miles away, and the antenna barely budged, lightly bouncing at the most. Quite obvious when you see an antenna's elements "culing back like blown grass" something is amiss.

I tried an experiment one time and I made a scale model of the yagi I have. I made a crude windtunnel from a 20 inch fan and kicked it up to high and placed the antenna on a post so it would swivel. Whenever the fan would be turned on, the antenna "rotated" and locked into what it saw as "least resistance" and stayed there like a compass finding North.

So a helpful hint. The next time there is a strong wind or storm, watch out for the lightning!, point your element ends into the wind and take a look. Wait for the nexxt storm, I wouldn't recommend rotating anything while a storm is in progress, then rotate the beam head on into the winds and see the difference.

Jeff Y.

620. Butternut HF5V-III wont tune on 20 Meters pse help

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-09 06:16:08 UTC
From: Eric Bourlet <ebourlet@gte.net>
Message-ID: <IeR_7.482$gt2.156612@dfiatx1-snr1.gtei.net>
Source record: 151257

I have recently resurrected an old Butternut HF5v-III. My problem is that it will not work on 20 Meters. The manual says that it should have a low SWR on the entire 20 meter band and no tuning is required. I have the 1/4 wave 75 ohm section and measured the velocity factor so I know its the proper length. Do you have any Idea what other problems there may be ? I am feeding it with a 30' section of rag-58. Thanks for any ideas you can provide.

621. Vertical tuned with AH-4 - Question on radials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-09 06:37:41 UTC
From: jim@bay-tech.com
Message-ID: <3c3be369.272385499@news.uslink.net>
Source record: 151258

I'm planning a vertical tuned remotly with an ICOM AH-4 remote tuner.

This will be an element of about 24' so as to avoid 1/2 wavelengths on the frequencies to be used as suggested by Icom so the tuner will work properly.

While I understand the importance of radials, I'm at a loss in this case as to how long they should be.

The antenna will be used on 160 thru 10 and the AH-4 will tune the vertical element - but what about the radials? Should they be 1/4 wavelength for each of the bands to be worked or should they be 24' also like the vertical element?

Help!

1) The sizes (dimensions)of the transmit and
receive antennas were reasonable for the BC band,

2) In the early 1920s receiver and transmitter
design and available components were OK for the BC
band frequencies, but not OK at short wave
frequencies.

A good example is FM, which was moved from the 40
kHz region to the 100 MHz region after WWII.
Technology improvements made it possible

A friend of mine, a physicist and amateur radio operator for long time,
constructed an EH antenna and this antenna seems not working at all
(signals are 20dB lower than those obtained with a full lenght dipole
installed low over the ground and somewhat folded for space reasons).
I was just curious to know if anyone else conducted similar test
knowing what he/she was doing (as my friend without no doubts did).

Thanks again and best regards.

Connect the center conductor of the coax to the antenna connector.
Connect the braid of the coax to the chassis of the radio. That
might be one of the screws that holds the radio together.

Reg wrote:
"So you don`t disagree with the maximum power theorem.."

It`s irrefutable. I wouldn`t want to recycle the 47KW CB and Conjugate Match threads. My argument in those threads was that some transmitters are not tuned and loaded for a conjugate match.
Perhaps more transmitters are matched to their loads than I realized, and perhaps it is their maximum power out which is adjusted in a way which limits them.

The old threads convinced me that the internal resistance of a Class C amplifier is set by the time it spends switched-off. It dissipates no power while switched-off. So, there`s your dissipationless resistance.

This is an abundance of sparks. Hope there is no combustible material around.

Best regards, Richard Harrison, KB5WZI

In <a1gv7c$7t9$1@freenet9.carleton.ca>, ab528@FreeNet.Carleton.CA (Heinz W. Wiggeshoff) writes:

I can't resist the rerun!

>Wes Stewart (n7ws@yahoo.com) writes:

> Damn, that speech recognition software is wonderful. We'll forgive
> the fact that it buggered up the spelling of 'Wes' though.

When OS/2's VoiceType and run the Desktop by voice first came out I tried mightily to train it for my voice! It just wouldn't. Part of the reason is that after ten years of telemarketing trailer dealerships, I'd developed a pattern of auction jargon in my normal speech! In a fit of anger I chanted into it:

Mary had a little sheep
with which she always went to sleep
the sheep turned out to be a ram
now Mary has a little lamb

I honestly got back:

Maria handsome ladle cheap
and Pentacostal witch to seep
Le cheap burned out Toshiba ram
Maria handsome little lamb

In studying how this actually seems to come about, I learned that auction jargon patterns really confuse the speech engine troops, although they are completely understandble to people! It's easier to talk for hours this way and still go home with a voice! (Becomes homewidavoice!)

The speech habit pattern which gets the voice recognition engines, seems to be, as in the above, where if you listen closely I'll sound something like:

Mary-hadda-liddle-lamb

which is the alliterative form of speech like we hear in the Gilbert and Sullivan songs! If you examine the phonic pattern in the little snip above, and chant it out, you'll find that it really is easier and faster to say it that way, than to more properly and clearly pronounce it!

Talking like an auctioneer is really quite easy.

For example, say,

What will he bid for ..

Then say,

Whaddlehebidfor

There's the example of the up-down toungue roll that is involved!
Rapidly saying these two patterns alternatively will you show you
exactly the thing which really confuses these engines! As you learn
more and more to do this, your speech pattern shifts to an 'automatic'
inate recognition of the chance to save a little bit of effort! From
then on away it goes!

Of interest in the thread, specifically, IBM has just announced, per the
trade rags, that a much improved meaning-aware version of ViaVoice is to
be released this fall. The original voice recognition toolsets that IBM
derived and dropped into the public use from the main-frame listen to the
phone lines and tell where the threat came from research, were there even
for the original OS/2 introduction of the technology. However, the
claim is that by fall, a major improvement will be at hand. They'll be
doing far better look backward - look forward over many more that the
two or three words that were the level of this bound into original ViaVoice.

That's one place where we really might see improvement from multi-Ghz
CPU's and huge amounts of really fast memory!

I still, as per the original poster, though, wonder what's going to happen
when someone really wants to say "Witch Witch!" And we still get back
"Which witch?" After Mary, I'm not convinced yet that even a 3.5Ghz CPU
processor speed and 512MB of RAM will let us even yet unravel the real
cause of the confusion to the engines!

"No never?" "No never!" "No never?"

Robert wrote:
"Does someone know an amplifier which can selectively amplify a weak frequency as shown on the following picture?"

The picture is not clear enough for me to read the frequency. So, I can`t give a good answer. There are kit makers to be found with websites showing preselector / preamplifiers. You may need to adjust coils for your specific frequency.
Search!

Larry see URL: http://www.cebik.com/bookant.html

Cubical Quad Notes: Volume 1 A Review of Existing Designs: This first volume reviews many
existing designs of both monoband and multi-band quad arrays to assess both the potentials and the
limitations of these antennas and their feed systems.

Cubical Quad Notes: Volume 2 Rethinking the Quad Beam: The second volume examines the
most fundamental properties that determine quad performance and develops computer design
programs for a number of monoband quad beam types, from 1 to 4 elements.

I wrote:
"The picture is not clear enough for me to read the frequency."

UKW is ultra short wave, or the FM band on my old German radios. So, I guess Robert wants to separate FM stations. In the U.S. these are no closer than 200 KHz. At a carrier frequency of about 100 MHz, that`s a separation of only 0.2 percent, or too close to separate with a single tuned circuit at the carrier frequency.

The superheterodyne has a lot going for it!

Best regards, Richard Harrison, KB5WZI

Hi all,

I'm a quad antenna fan. I've built some arrays for the 6 meters band
with great satisfaction for me. Now I'd like to build a two element
quad multiband antenna for HF (let's say 20,17,15,12,10 meters for now)
and I'm looking for practical notes on contruction of such antennas.
In particular I'd like to learn what are common used ways to feed these
antennas (multiple coax, single coax with switches, single feed in
parallel to all radiators maybe...) and how to arrange element for
different bands (same spacing VS different spacing on each band...).
Any info about these antennas is welcome.
Thanks in advance and best regards.

> makes it the best choice?

Long wave less than 500 KHz was deemed necessary for long haul
communications.
Short wave more than 1500 KHz was deemed to be useless for serious
communication
and was assigned to amateur use. Broadcast was slipped in to that plan at
the shortest
wave length that was still useable.

Message-ID: <3C3C7A9F.B6AAB65A@blackhole.net>
Source record: 151135

Playing with an antenna modeling program, I found that having the last 6 feet of a 30 foot wing of a dipole angled downward from the antenna made the antenna have some circular, or at least mixed, polarization.

That got me to wondering what circular polarization means.

1. Does it mean that the angle of polarization of the em wave changes within each cycle as it passes the receiving antenna? That would seem to be what would happen as the wave from the dog-eared dipole passed the receiving antenna.

2. Is circular polarization a yes/no thing, or can it be partial? Is it really circular, or could it be, say, oval or triangular if you had a funny shaped antenna?

3. Might an antenna have different polarizations in different propagation directions?

4. In an ideal case, what would be the relative loss receiving a perfectly circularly polarized signal on a horizontally polarized antenna?

Circular polarization means that at a fixed point in space, the total
electric field vector of the EM wave radiated by the antenna traces out a
circle as a function of time. See more details below.

> 2. Is circular polarization a yes/no thing, or can it be partial? Is it
> really circular, or could it be, say, oval or triangular if you had a
> funny shaped antenna?
>

In general, all antennas are elliptically polarized.

Consider the radiated EM wave at a fixed point in space away from the
antenna. The total electric field vector of the wave has an Ex component
and an Ey component. At this fixed point in space, the total electric field
vector would trace out an elliptical shape as a function of time.

Pure circular polarization is a special case of elliptical polarization
where the Ex and Ey components have equal amplitude and are 90 degrees out
of phase.

Pure linear polarization is a special case of elliptical polarization where
either Ex or Ey is 0. In this case, the total electric field vector traces
out a straight line as a function of time.

> 3. Might an antenna have different polarizations in different
> propagation directions?

Yes.

>
> 4. In an ideal case, what would be the relative loss receiving a
> perfectly circularly polarized signal on a horizontally polarized

> antenna?
>

In an ideal case, where the circularly polarized wave has 0 dB axial ratio and the antenna is purely linearly polarized, the relative loss (polarization mismatch loss) is 3 dB. The linearly polarized antenna "sees" only 1/2 of the energy in the circularly polarized wave.

In general, the mismatch loss is something other than 3 dB because it is unlikely that the "circularly polarized" wave has an axial ratio of 0 dB. The axial ratio is the relative field strength difference between the Ex and Ey field components expressed in dB. For example, if the circularly polarized wave has an axial ratio of 3 dB (quite common) then the polarization mismatch loss will vary between 1.77 dB and 4.77 dB depending on how the linearly polarized antenna is aligned wrt the circularly polarized wave (how it aligns with either Ex or Ey).

Jim,
There are two schools of thought about radials. One says
to use 1/4 wave radials on the lowest band you plan to use.
The other says to use radials the same length as the vertical,
but more of them. Take your pick. (The 'lot more of them' and
as long as the vertical is much easier to do for most people)
Your going to have fun on 160-40 meters. That 24 feet is
kinda short for those bands, especially 160 and 80 meters.
Good luck...
'Doc

We have a few of these excellent handbooks left from the holiday promo.
Its the latest 23rd edition, the hardbound bible of builders and superb
classic reference
for all areas of interest to hams.

Bill/W6SAI lives on via his many gifts of articles and books. His
writing methods allow all levels of technical backgrounds to understand
and learn from his expertise.

The Handbook normally sells for $52.95, plus shipping and tax in state.
We're selling them for $39.95 plus a flat $5 shipping within the US 48.
That's $44.95 total! You can order online or call,fax, email.
Follow this link for more information:

Yes. It is often found that sideways on to a horizontal Yagi, best
reception is from a vertically polarized aerial.

Alex wrote:
"If I bring the radio close to a window, reception is perfect."

Some old Zenith Transoceanics had "Wavemagnet" loop antennas with suction cups to attach them to outside windows. The Wavemagnet cable wasn`t 25 feet long. Never mind. Get yourself one of these old working models and make yourself a flat cable extension cord. Snake the extension cord under the carpet between the Transoceanic at your workstation and the window with the wavemagnet. This particular Transoceanic may not work with this configuration, but some variation of this will work. You need low-impedance loop output (a turn or two), and a low-impedance radio input (balanced could be less noisy). Cable between the loop and radio is low-impedance, parallel-conductor, twisted pair, coax (not balanced but could be quiet too), almost anything will do.

Best regards, Richard Harrison, KB5WZI

Reg Edwards wrote in message ...
+AD4-It is popularly understood that an increase in soil resistivity always
+AD4-results in increased losses in the ground such as the ground in the
vicinity
+AD4-of a vertical antenna.
+AD4-
+AD4-But this cannot be true because when soil resistivity increases to the
point
+AD4-when it can be considered to be an insulator the ground loss becomes very
+AD4-small again.

Yes, but then the wave would continue to propagate into the soil just as if it were in free space and for your purposes it would be all loss.

The greatest losses therefore are when the soil appears the same as free space, then all the wave is absorbed, none reflected.

Interesting question

Give it a break. Every time I see someone bitching about something like this, I'm tempted to post this response. This time I am.

I, for one, would be happy to drive half way across the country (actually it is more than half way) if I was in the market and had the $$ to buy it. If I'm in the market and can't find something like it locally, it's worth the time off and travel to go pick it up anywhere in country. It's also worth it to me to be able to look at it before I hand over the check and be sure it's what it's supposed to be, and to handle it myself, instead of letting some Joe Schmuk trucking company do it.

I've sold things to people who drove several hundred miles to pick them up. I certainly have no problem being on the other end of the deal.

I have read parts of Walter Maxwell's book Reflections II. He mentions the conjugate matching theorum. I still don t really understand it. In simple terms can somebody describe it and how it affects transmission lines, matching, antennas, tuners and getting the antenna system to operate efficiently?

Also why doesn't ARRL Antenna Book or Joseph J. Carr mention it in his book? (Why) or is it controversial?

Does anyone know just how far the local zoning officer can go with dumb ordinances involving antenna heighth and proximity to property lines, ect? Our local ordinance says an antenna mounted on the ground can't be

above 15 feet high, but a roof mount can be up to 20 feet above the highest point of the roof. I have mine on a 30 foot tower anchored to the gable of the roof. I also have a ground plane on the other side of the house that's close to the FCC limit of 70 feet. Do these local ordinances overrule the FCC? Where can I get the definitive answers to the questions I need to ask? Any help you could provide would be greatly appreciated. I also should mention that he said I could have only one antenna. Has anyone ever heard of this? Is this enforcable? I might just give him what he wants and take the one down and change the

dual polarity to a five element flatsider right about the height of the telephone lines and tell him to go @#$% himself. Thanks for any help you can give me with this problem.

It would be better if you first understood the DC maximum power transfer theorem. That theorem says that maximum power transfer occurs when the source resistance is equal to the load resistance. The Conjugate Matching theorem is the AC/reactance equivalent of the DC theorem.

At one time, the maximum power transfer theorem was used to "prove" that central power generation and distribution was but a pipe dream. Then they discovered efficiency.

Point well take Jeff. I cannot disagree. However the point I was making was not to oppose the structure or operation of either antenna, but rather the differences I have encountered in the use of both. Turning the elements into the wind is helpful for preserving the Yagi type antennas, untill of course you have several stacked. The primary reason for my changing to a single boom type (reguardless of structural type) has more to do with the overall windloading I am presenting to the top of my Rohn Tower. The Quad simply exhibits a fraction of the side/side moment and less compression on the tower. Hurricaines are fairly easy to predict which way the wind is coming from, However, we tend to get some real ugly t-storms that vary greatly in wind intensity and direction. At that point, your'e guess is as good as mine.

Those swirls, downdrafts and crosswinds can really play haviic on them, not doubt, but it still better to get a good idea which way the winds are generally coming from and take the proper precautions.

I'm used to the fact that being from the snowbelt states that just about everyone I knew who had a quad lost one due to the ice and in some cases survived the ice but failed when a moderate wind, 20 to 25 MPH, came along and with the extra weight totaled them. I know it's not the same situation but I thought I'd point that out as well and where my view was coming from.

BTW, what size Tohn tower are you using? 25G, 45G?

Jeff

Hi Jerry.

I've read the other "replies" to Your question with astonishment.
Noone tells You what it is about.

Conjugate matching for Newbies:
==========
The output impedance of Your transmitter is "marked" 50 ohms.
This is RESISTIVE.

An antenna that is to "short", a GP shorter than wavelength/4
ACTS like a capacitor in series with a resistor. If we for
simplicity assume that this "resistor" is 50 Ohms, You will need
a coil to match the antenna.

Now, assume that we can connect the antenna WITHOUT a
transmission line:
If the reactance of this coil is equal to the reactance of the
"antenna capacitor" multilpied with (-1), you have matched the
antenna. So, You need a Coil between tha antenna and the
transmitter. The properties of this Coil can be calculated.

If You have an antenna to LONG, it will act like a Resistance
in series with a Coil, and You will need a capacitor in series
for matching.

Reactance is a form of "AC resistance", but the Current Trough
a Reactance is out-of phase with the Voltage, so that NO POWER
will be dissapted. That is, the formula P=R x I-squared for
a pure Reactance (X) is instead Zero = X x I-squared.
As Capacitors are (more or less) pure Reactance, a capacitor
will not be warm if a current runs trough it.

To describe in simple terms how this affects transmisssion lines
can not be done. This is REALLY HARD, unless You have a
M.Sc. degree. Anyone who claims it different, is fooling You.
This is the probable reason why it is NOT in the newbie handbooks.
There is a very famous tool, the Smith-chart, which gives a grapic
wiev, that can be used without REALLY understanding what is
happening. This still is in use in this compitized age. But, in
my (very old) edition of the Antenna book, the Smith-charts ARE
descibed. So, my guess is that the Conjugate Matching Theorem
IS there, but perhaps not explicitly...

73 de V.

> on 94.0 and 94.7 MHz.

I don't think you'll find an amplifier that's selective enough to amplify the signal you want without also amplifying the other two.

Can you use a directional antenna? - if the signal on 94.3 is from a transmitter that's in a different direction to the other two then you may be able to increase its 'relative' strength that way. Having said that - the two signals you don't want are very strong by comparison with the one that you do want....

Hope this helps

94.7 is likely another FM station, interfering with 94.3 MHz. The signal
on 94.0 is even not odd, so is likely something other than an FM
station.

The difference in frequency between 94.7 and 94.3 is 0.4 MHz.

0.4 / 94.3 = .004

105 MHz may be the frequency used to convert received frequencies to
10.7 MHz for IF amplification. It will be the local oscillator frequency
in our example when the received frequency is 94.3 MHz.

The difference frequency when the interfering 94.7 MHz is beat against
105 MHz is 10.3 Mz.

The difference between 10.7 MHz and 10.3 MHz is 0.4 MHz.. This is the
same difference in the desirerd and interfering frequencies as before
the frequency conversion.

0.4 / 10.7 = .04

The difference as a part of the carrier frequency is vastly different.
0.4 / 94.3 versus 0.4 / 10.7.
The frequency ratio for the IF amplifier is almost 10 times better for
the separation of the interfering frequency from the desired frequency.

If you must have a 94.3 MHz signal cleaned of the interference, you
might hetrodyne the signals to 10.7 MHz, filter out the interference,
then reconvert the desired signal to 94.3 MHz.

A directional antenna would be the first effort.
If you are handy with VHF construction, you should be able to make some
simple traps for the adjacent stations that would allow you to amplify
the weaker signal.

AstroMan:
You may want to check the discussion of this topic on
alt.folklore.urban.
Googling for "cell phone airplane" in group alt.folklore.urban brings
up
a post on 9/19, regarding the "handoff problem" of cell phones, and
how some types, especially CDMA systems should work better, even when
in view of several towers.

My thoughts on this:

1) Central PA doesn't have as many cells as, say, New York City. As
such, the area covered by one cell may have been large enough to
prevent hand-off problems.
2) The Doppler shift depends on the radial velocity, not the absolute
speed. Passing a cell is like having a satellite overhead-- no
Doppler shift.
3) In an emergency, systems which are not reliable can be made to work
well enough-- no one said the cell phone calls were "pin drop
quality".
4) Why wouldn't the terrorists simply turn off the Skyphone circuit
breaker?

The search also brings up a nice quote from the Philly Daily News,

"No one has fully explained why the plane went down, or what exactly
happened during an eight-minute gap from the time all cell phone calls
from the plane stopped and the time it crashed."

No one said "Skyphone", and, if it had they might have said "after
the Skyphone went dead". That makes me feel more comfortable with a
non-centralized system like cell phones, rather than a centralized one
like Skyphone. Still, I'm open to evidence.

Jerry asked -

> Why doesn't . . . . Joseph J. Carr mention it in his book?
==========
Hi Jerry,

He's following the great Frederick E.Terman in 1943. It's such a trivial and obvious matter it's not worth printer's ink.

William.L.Everitt, "Communications Engineering", made passing reference to it in 1932 AD and then dropped the subject without a thud. If you insist on an authoritative reference then his brief, simple, easy explanation is fine.

But expect letters of thanks from Internet dot.com service providers for resurrecting the subject. Do you hold shares?

Oh, by the way, the theorem, if it can be described as such, has no special association with radio transmitters and feedlines.

And when reading the many, varied, often conflicting explanations you may be offered on this newsgroup or from other sources, be on your guard against being led into the false belief the internal resistance of radio transmitters is 50 ohms - it isn't.

Peculiarly enough, conjugate matching to antennas applies much more to receivers than it does to transmitters because we do at least have a good idea of what the input resistance of a receiver is.

A conjugate match exists when the load resistance is made equal to the internal resistance of the generator and, if necessary, the sum of the generator and load reactances is tuned out (reduced to zero) by an additional series reactance. This is the OBVIOUS and indeed the ONLY way of delivering the maximum power available from any generator into a load.

Regarding radio transmitters, mere delivery of maximum available power is seldom the objective and conjugate matching is not applicable. When it is applicable it is done without even thinking about it. The colour of the plate is of greater interest.

Val wrote:
"Reactance is a form of "AC resistance", but the Current Through a Reactance is out-of-phase with the Voltage, so that NO POWER will be dissipated."

Reactance is a form of impedance.

It was admirable of Val to attempt a short course in electricity but it is important to note that reactance has a 90-degree relationship between voltage and current, not 180 degrees, etc.

"AC Theory and Reactive Components" is a chapter in the ARRL Handbook. There are enough pages and illustrations to avoid some misconceptions from shorter treatments. Many other texts cover the same material and those and the Handbook are the places to look for a-c basics.

Some texts have good explanations of the maximum power transfer theorem for both a-c and d-c.

Reg wrote:
"It (a conjugate match) is such a trivial and obvious matter it`s not worth the printer`s ink."

Yes, but, a conjugate match at an antenna-transmission line junction is required to avoid rejection of a part of the power presented by the transmission line to the antenna. That rejected power is called a reflection. Sounds like a thoughtful book title.

Reflected power on a transmission line depends upon the antenna load matching the Zo of the line.

The power a transmitter is able to deliver into a Zo-line depends on how the load presented by the Zo line, whatever it is, matches the transmitter`s internal impedance. The Zo of the line is not what is matched because, for example, the transmission line could be a 1/2-wavelength of any Zo and deliver a transmitter load of exactly the same impedance as presented at its far end.

A conjugate match between the transmitter and its load permits extraction of maximum power from the transmitter.

Jerry:

Trolling trolling trolling over the sparkling sea...

MAXIMUM POWER TRANSFER THEOREM - sometimes called thed CONJUGATE MATCHING THEOREM --

Heh, heh... our picayune Mathematician colleagues would scoff that we techies glorify such a simple result with the title of "Theorem". At best they might call it a "lemma" or simply "an exercise left for the student". Remember your Math teachers?

In *plain* English words the so-called "Conjugate Matching Theorem" is stated as follows:

*** The value of a load impedance (Zo) which, when connected to a given source of internal impedance (Zi), maximizes the real power delivered into that load from the source, equals the complex conjugate of the internal impedance of the source. ***

Note: A point often missed, must be a subtle one I guess, is that this so-called theorem is a "load designer's" theorem.

It does not work the other way round! That is, the theorem is useful to anyone desiring to optimize a load Zo, when given a Zi, BUT is not of much use to those desiring to optimize a an internal source Zi to a given load Zo!

The optimum value of the internal source impedance required to maximize power into a given load is quite a *different* result!

Using mathematical symbols, the conjugate matching theorem can be stated as follows: if the internal impedance of the source is experessed as Zi = Ri + jXi, then the optimum load impedance Zo is equal to the complex conjugate of Zi, namely Zo = Ri - jXi.

Where: R is resistance, X is reactance, j is the imaginary unit from complex number theory, and those two catchy words "complex conjugate" simply mean, change the sign of the imaginary part. i.e. change the sign of the reactance!

A special and often encountered case is when only resistance is present and X is not. If reactance X is not present in either the source or the load, then X = 0, and Zo = Ro = Zi = Ri is the optimum solution. i.e. make the load resistance Ro equal to the source resistance Ri.

(Practically this means that the presence of reactance, in either the source or load, tends to prevent the optimum transfer of power, and that this can

be fixed by "cancelling" inductive reactance in one with an equal amount of capacitive reactance in the other or vice versa, before adjusting the load resistance to equal the source resistance.)

A mathematical proof of this famous conjugate matching theorem result requires the use of methods of differential calculus. It takes about 5 or 6 lines. to prove it, an outline of the proof is: write down an expression for the real power Pr dissipated in the load Zo, in terms of Zi = Ri +jXi and then seek the values of Ro and Xo which yeild the maximum value for Pr. This is usually done by taking the derivatives of Pr with respect to Ro and Xo, namely dPr/dRo and dPr/dXo and setting them both equal to zero and then solving the resulting two simultaneous equations for Ro and Xo in terms of Ri and Xi. The simple end result of this manipulation is that Ro = Ri and Xo = -Xi.

Below here are the gory details that the Mathematicians see as "too elementary to be a theorem". Do ya'll agree!: Note that EE texts leave this as an exercise for the student. Below is the "proof" completely worked out... straight from the EE Professor's solutions manual! Worth 20 points on the next EE freshman mid-term quiz! Heh, heh...

Maximum Power Transfer Theorem:

Given an electrical source of voltage with intenal impedance Zi = Ri + jXi, find the value of the load impedance Zo = Ro +jXo connected to this source which results in the maximum power delivered to the load.

Without loss of generality assume that the open circuit voltage of the source is unity (one volt rms):

The real power delivered to the load Zo can then be expressed as:

Pr = Ro/((Ro+Ri)(Ro+Ri)+(Xo+Xi)(Xo+Xi))

Taking derivatives of Pr with respect to Ro and Xo, and setting them both equal to zero, which defines the maximum of Pr, we get the following two equations to be solved simultaneously:

(1) dPr/dXo = -Ro(Xo+Xi)/((Ro+Ri)(Ro+Ri) + (Xo+Xi)(Xo+Xi)) = 0

2) dPr/dRo = ((Ro+Ri)(Ro+Ri)+(Xo+Xi)(Xo+Xi) - 2Ro(Ro+Ri))/((Ro+Ri)(Ro+Ri) + (Xo+Xi)(Xo+Xi)) = 0

Noting that both equations share a common denominator, namely ((Ro+Ri)(Ro+Ri) + (Xo+Xi)(Xo+Xi)), that the numerator of (2) has a common factor (Ro+Ri) on both sides of the minus sign, and eliminating these coomon factors, we get two more compact equations to be solved simultaneously for Ro and Xo which maximize the power Pr, in terms of Ri and Xi.

(3) Ro(Xo+Xi) = 0

(4) (Ro+Ri) + (Xo+Xi) - 2Ro = 0

Clearly from (3)

Xo = -Xi

and substituting this value of Xo into (4) gives

Ro = Ri.

As the Mathematicians say...

QED

Another way to look at it is to imagine having a dipole antenna that is rotating, in a plane broadside to the direction of propagation, at a rate equal to the transmit frequency.

That is, if you are transmitting on 7.000 MHz the dipole will be spinning at 7000000 revolutions per second.

In free space the polarization will be the same at both ends. However, as you introduce objects (electric wires, street lights, signs, houses, etc) they will absorb and reradiate the signal (commonly called 'reflections'). The resulting composite signal will have random polarization, and possibly become circular! It depends on the relative angle between the object and the incoming wave polarization. The same thing happens with multihop HF propagation.

In general, a "conjugate match" at the junction between the antenna and the transmission line does not prevent reflections from being created at the antenna. Only when the antenna impedance equals the Zo of the line will there be no reflections. In general, a conjugate match and an impedance match are not the same things. A conjugate match and an impedance match will be the same when the source impedance exactly equals Zo.

It is easy to set up an example where more power is delivered to a load with reflections (the conjuagte match) than to a load where there are no reflections (the impedance match).

> Reflected power on a transmission line depends upon the antenna load

Yes, and this condition is not necessarily a conjugate match.

Jerry,

Conjugate matching is what happens, when you are coupling the 50-ohm output of your transmitter or amplifier to a load that is not 50 ohm. You need some type of matching network such as a gamma or beta match or an antenna tuner.

For example when you adjust your antenna tuner so as to obtain a VSWR of 1:1 you are matching the 50-ohm transmitter to the complex impedance of your antenna system and by system I mean the antenna and transmission line.

Let's say that the complex impedance looking into the coax from the antenna is 60 ï¿½ j100 ohms. When you adjust your antenna tuner to a VSWR of 1:1 the transmitter is seeing 50 +/- j 0 ohms and the antenna tuner's output is still seeing 60 ï¿½ j 100 but if your were to measuring the complex impedance looking into the tuner's output connector you would measure 60 +j100. The tuner's output impedance is the opposite of the impedance looking into the coax. Since the antenna tuner's output is tuned to 60 + j100 and the complex impedance from the antenna system is 60 ï¿½ j100. The reactance values cancel out. This is conjugate matching. Picture it as if you were looking at yourself in a mirror. Raise your right arm and in the mirror it's appears to be you're left arm that was raised.

I hope this helps you. I tried to make it simple but it is a complex subject. However you are reading the right book.

Best of luck,

GW

(Peter's proof snipped.)

Very good, Peter. Now do the same proof
when the source resistance is "dissipationless." Don't neglect to tell how to
actually construct a "dissipationless resistor."
Moreover, for extra points, you may want to
explain how to incorporate all this into a
class C vacuum tube amplifier. If you want to
cheat, you can get your ideas from previous
posts to this newsgroup, but in that event, you'll get an "F."

Hi again Reg:

Sounds like a guessing game, now I'm guessing 377ohms per square if the antenna is a quarter wave away from the soil and is horizontal. This comes from having continuous E and H fields and having them be dissipated with zero reflection. This is also known as a "Salisbury Screen," and 377ohms is the ratio of E to H in free space.

Here's an arcane guess: You probably have to match 377 times (1 + tan(delta)) [where tan(delta) is the soil loss tangent] to the ratio of E/H at the soil's surface for a particular antenna configuration in order to have the soil suck up all the RF. This would be independent of polarization if the soil surface were isotropic.

Steve, VE9SRB wrote:
"Only when the antenna impedance equals the Zo of the line will there be no reflections."

Good point! The Zo of the line is practically a pure resistance. I should not have used the conjugate word as an adjective for match regarding the junction of the line with the antenna. Doesn`t make any difference what the impedance looking toward the transmitter is. It`s the impedance bump the forward wave encounters when it hits the antenna that determines the reflection from the antenna. The line forces the wave to conform to Zo, in both directions of travel.

Source record: 151088

Hi,

I'm currently planning a new (well, actually it's my first one) antenna tower.
Up to now I've been operating with a R-7 vertical so I don't have any reasonable
experience with directional antennas.

Maybe this question has been asked before:

Should I go for a cubical quad or a yagi beam?

I'm looking for good DX performance and coverage from 10m-20m (or even 30m).

I do have the space to set up a tower 30-40ft, so there's room
enough to accomodate a 2-3 element quad or 6-7 element yagi.
However I don't want to setup a "christmas tree" of 3 or even more
mono band yagis (which might offer max. performance).

Any hints / oppinions / "pros and cons" are appreciated.

Thanks in advance.

73,
Frank

I use "hamsticks" (Valor, IronHorse, Pro-Am) from my balcony in vertical
configuration with 1/4w counterpoise attached to base of stick. Works
FB (WAS and 73 DXCC since last March).
I prefer the kind that don't have a setscrew so you can remove the
stinger without changing the resonant freq each time.

I'd go with a "Non Cubical Quad, the ones with Convex end elements. The classical "Cubical Quad" does NOT have Convex end elements. 2 Quad elements = a true 3 Element yagi in forward gain. 3 Quad elements has slightly more forward gain than a 4 Element yagi. 4 Quad Elements you're crazy (Like Me).

Quad Advantages:
a) Bandwidth is slightly wider
b) Requires a lighter duty rotator than a 7 element Tri-Band Yagi. Less wind load, lower inertia.
c) Less sensitive to atmospheric noise
d) Less turning radius required, shorter Boom
e) No Lossy Traps
f) Probably cheaper depending on lots of things (Especially how it's fed)

g) Work better at medium tower heights (40' you said)
h) Front to Back ratios are at least 3 dB higher
i) I believe modern Fiberglass spreaders and aluminum spiders are as rugged as most (Not all) Yagi's regarding Ice loading and wind survival..

Quad Disadvantages
The Yagi will likely require no tuning (Unless you're real pickey).. you just adjust to manufacturer's recommendations and put it up. Depending on how you feed a quad, you'll likely have to mess with it some. If you run a single feedline, there will be element interaction effects that might require some fiddling. I'd recommend using a remote controlled coax switch, and feed each element individually with the proper 75 ohm matching section and choke balun at each element feed. Also having a Crank up/Tilt over tower will make tuning it a breeze.

Reminder: I've been called "Loopy" on this news group.

Source record: 151091

I have the opportunity to put an antenna up anywhere on a new tower. I just need to get the antenna and some hard line to the site. The more hard line, the higher it can go. A multi-band antenna would allow me to connect several different radio systems to it, but so far the only candidates are the 144/220/440MHz Diamond and Comet, fiberglass, about 10 feet tall, and I don't know if they'll stand up to the wind, so to speak.

Anyone have some ideas or manufacturers that I should look into? If I have to select just a single band antenna, it'll probably be 440-450 MHz, but that would limit me significantly. There must be some good monoband antennas that can be bought.

Thanks in advance.

Bob, WA1MIK

Hi Doc,
I'm sorry that there are people out there that have nothing better to
do, and have elected themselves the internet police, they need to
lighten up. I sold my TriEx Tower to a ham in Rhode Island who was
only too happy to pick it up. A ham trucker from 7 land is considering
the Hy-Tower and if he decides to buy it he may have a buddy trucker
pick it up for him when he passes thru the area, so you see there are
alternatives to shipping. I don't believe what I did was in any way
improper.
If I can't sell it, I'll reconsider my options.
Those who supported me, thank you, but I realize you can never please
everyone in this world.
It is still available.
Dave

I have had a 2 element 5 band quad up for over 5 years, it's feed with a single coax. It is at 75', it's been through high winds and ice storms. I try not to look up at it when the ice is heavy on it or the wind is blowing strong, it's a sorry sight to see. But it does take the weather well and works good even when ice covered. I do have mono band yagis for 10 & 20, both are 3 element, at times they do out play the quad, but on the same note the quad out does the yagis at times. I am now thinking about putting the 2 element quad on my 55' tower and installing a 40 meter quad on the 70' tower. I had a 4 element quad on 6 meters at one time, I also had a 6 element 6 meter yagi. For me the yagi out played the quad on 6 meters. I find the quads are a little more broadbanded than my yagis, front to back is about the same, the yagis seem to be tighter on the sides. Over all I vote for the quad on 10, 12, 15, 17, 20, 30 & 40 meters. Yagi on 6 and 2 meters. Loops on 80 & 160. I have never had weather damage to my quads, but I have on the yagis. I have several

friends that also have quads and like them. Any questions drop me a note.

Frank,

I purchased a 5 band spider Gem Quad (Canada) for several reasons:

1. All WARC bands, _and_ 6 and 2 meters!

2. Optimal (or at least better) spacing on each band. This has two effects: the SWR curves and F/B ratios on each band are a little better than the fixed-spacing quads; and the elements are a little farther apart from each other than on a fixed-spacing quad (reducing interaction between elements)

3. Ability to TUNE each band independently - so when I want to adjust tuning and F/B ratio on 10 meters it doesn't completely undo my settings for the other bands.

4. Ability to FEED each band independently - although I do not do it this way. I feed the antenna to match my rig and amplifier/tuner [Icom 746, AT500/IC-2KL] - so I coupled 10/12, 15/17, and 20 meters is alone.

5. Lightweight, tight turning radius - I have this on a 56 foot fold-over tower with a medium rotor on a heavily treed lot, and can drop it to the ground and work on it single-handedly.

6. Previous positive experience with a quad on HF... low noise, good bandwidth, great for DX; along with negative experience with trapped tri-banders (ugh!).

Now, having said those positive things, I will also add that tuning the quad is a labor of love and requires patience. I would not even attempt it if it were not easy to drop the quad and adjust it (crank up, fold-over, whatever - or you gotta' love climbing towers!) and unless you own an MFJ 259 antenna analyzer.

You must have some problems with that many bands on a single coax. Frankly, I never tried a single feed Quad. Full size 3 el. Mono-Banders are tough to beat with one 2 element multi-band quad, and if you prefer the Quad, I understated my enthusiasm for the Quad!

Hello Frank:

I have had monobanders, trap arrays and quads during my 33 years as a ham...I very strongly favor a WELL TUNED quad over any other antenna. I consider a little known company, GEM QUAD PRODUCTS, in Canada, the premier quad antenna in the 10 through 20 meters field. I currently use a 2 element Gem Quad at 38 feet and it has been praised by reports from DX'rs in California (my QTH) as well as around the world. Tests done under certain band conditions give performance results that are not theoretically possible with a 2 element quad, like > 50 dbs front to back...of course, this has been done with regular radio S meters and not with lab equipment....

I did my reflector tuning with a very simple procedure by using an SWR analyzer instead of the normal S meter reading of a receiver.... If you are interested (or anyone else), please e-mail me at the QRZ.com e-mail address and I will be happy to send the procedure, or if someone can tell me if protocol allows me to attach a file to a message, I will do that.

The major problem with Quads is that it is a 3 dimensional antenna and the assembly and tower mounting is usually not very easy, so, lots of planning is suggested.

Any questions, I would be happy to answer....(I'm very active on CW/SSB 10 through 20 meters daily)

hey mark
in your opnion what would you rather use for VHF 4 cushcraft 13b2 or 4 10 ele
cubical quads?

Mark Hall wrote:

Good thinking, Mark, I think you hit it! You will get total absorbtion by the ground when the ground impedance equals the wave impedance or a thin slice of 377 ohms/square material if in the far field or at wl/4 from the antenna. This is called a Salisbury shield but I don't know how you would apply it to the near field of an antenna where the ratio of E to H is not exactly 377 + j0.

Cheers to Reg for thinking of the question and ciao from me,

Mark, the single feed works great. No different than using a single coax to feed multiband dipoles. Of course I'm not a real fussy type person. As far as SWR the quad covers most of all the bands with no problems, even the amp don't complain. I can't see as adjusting one band on the quad has has any effect on the others. But as someone else said it is a job doing the adjusting to start with, especially if you don't have a fold over of lay over tower. I do see the quad likes to hear my neighbors electric fence a little better than the yagi's do.

Well.. I don't do VHF, but if I did, maybe I'd try 4 helixes in phase, or maybe a shortened, ground counterpoised vertical with a ton of radials buried. Sorry, I'm only "Loopy" on HF, I'll leave the VHF'ers alone!

HaHa! A pair of dykes would solve that Electric Fence problem! Maybe you could couple into the Fence on 80/160 and make up for it? I've never heard of an Quad for those bands.

Need a little more information. How much wind (max mph gust speed?) Any icing? Need allot of gain out of your antenna? Or would 3/6 dbi be OK? Instead of expensive hardline (which is the best of course) would a run of Time LMR400 ;or another Time product do you?

I am using a Diamond 500 m(12ft?) at one site and a Diamond x-50 (~3ft) on another. I like them both. If wind velocity (excess of 90mph) is an issue, then go with the shorter model, but then you are giving up gain. Both have served me well. Yes, I know they are not commercial grade, but they are doing the job and I haven't got allot of money rapped up in the system.

Hey, hello and Happy New Year, what... only an F!!! For a treatise on
"dissipationless". What?

Well David Reyburn, W8EZE, he's a former Math Prof, already gave me a B-
because of errors and omissions in my proof of the matching theorem.

I think David's comments are valid, he provides corrections to my proof, and
my reply to him are worthwhile and so I'll post them here below...

[begin post]--------------------------------

David:

[snip]

Nice to e-meet you here.

Hey thanks for the "corrections" to my "theorem" proof. I hope that you
have posted them to the NG as well! I certainly will.

[snip]
> Picayune? Come on. One man's theorem is another man's counterexample ;-).
[snip]

Heh, heh... I hear you!

[snip]

On the saddle point possibility in the Pr objective function maximization, and the need to check the second derivatives, you are correct and indeed for a full "proof", that possibilty needs to be checked.

However, although I have not done so in the NG posting, an examination of the quadratic forms involved in a complete development of linear dynamic system energy relations you can assure yourself that the surface of the objective function Pr is indeed convex and that there is only one maximum. For the more pragmatic among NG readers, a simple graphing of the surface of Pr over the Ro, Xo plane will suffice. Too bad we can't post graphs on the NG, I have a nice one here in my full document.

[snip]

[snip]

Agreed! In fact I had that factor of 2 in my original MathType MS Word document and missed in during translation/typing into plain ASCII text for the NG posting. Sorry...

[snip]
>
> >2) dPr/dRo = ((Ro+Ri)(Ro+Ri)+(Xo+Xi)(Xo+Xi)

[snip]

Agreed... you are correct again...

The usual formula for the derivative of a ratio of two functions from
elementary differential calculus involves the square of the denominator
function in the denominator of the resulting derivative.

[snip]

[snip]

David, a more general approach would follow the "usual" development of the
energy relationships in linear dynamical systems and would result in a set
of quadratic forms from which the unimodal nature of the objective function
could be established.

[snip]
>
> >As the Mathematicians say...
> >

[snip]

David... Nice to have a "pure math" guy here to keep us honest. sfu, huh... Last time I was up on Burnaby Mountain, I was meeting with Don George... a pseudo-mathematician, but a great engineer. Did you ever lecture to the Engineering, students at sfu? Where are you located now... did you leave Vancouver/Burnaby after retirement?

BTW... It so happens that I generally use MathType V.4 as an equation editor running inside MS Word for mathematical developments myself, what equation editor do you use? I've got pretty good at MathType over the years and they keep on improving that little product... nice.

Indeed I did develop that little max power transfer "proof" using the MathType tool as an editor. I then painfully translated the MathType into plain ASCII text for posting to the NG... I could send you an ADOBE version of the full document in "real" math as an email attachment if you like.

Although I have not vetted all of your suggested changes in detail, I note that most of your assertions about my "sloppy" proof are correct because I do see my dyslexic "mis-typing" in executed by my aching fingers while translating from my MathType document to the plain ASCII text for NG posting.

I translated things like (Ro+Ri)**2 (Excuse the Fortran_ism!) into (Ro+Ri)(Ro+Ri), etc. and I admit that I missed the typing factor of 2 in the numerator of which you speak despite it being in my original documents.

Thanks for keeping me honest... I know there are more than a few on the NG who suspect me of trying to obfuscate, but I assure you my intentions are always honest! Heh, heh...

In theory theory and practice are the same but in practice they are different.

Best wishes for the New Year and thanks again.

Actually I have 80 ft of 25G up hosting the Quad. even though I could
go higher, I still like to be conservative. I plan in the near future
to put up a 2 element yagi, or Quad on 40, but not on 25G. I think
better on 45G or larger. Get enough widloading up on one of these
toothpicks and they'll corksctew down. I also use the guy brackets
with 4ft long steel arms for the guy attatchments. This helps minimize
the twist, even on sudden stops from the rotator. When considering
erecting a tower, there's no such thing as overkill. Build to the best
of your budget can allow. I dont run any antennas with longer boom
legth than 30 ft. Longest was 34.5 ft. The Hygain 205. Even that was
pushing the limit. I still drive down rural roads and look at the High
voltage lines across the towers that carry them, and wonder what's the
best way to mount a rotator on one - hi hi.

My experiences favor the quad, reasons listed in a prior posting here.
Dont underestimate what a quad can do on VHF. I cant wait to get
6 on six. If all goes well, I'll build a second and stack em. I've
just got to do something with those 10 watts. I tend to recieve
nearly Identical reports on DX (HF htat is). running 100 watts to a
4 element Quad. It does seem a little more forgiving to height above
ground, however It still has to adhear th the same electrical
characteristics of Yagis. I have Yagis also on HF. Not a tramendous
differece in performance. Perhapps slightly more quiet. Prefered
antenna simply due to the ability to stack 5 monobanders on one boom.
No traps, induvidual feeds. On the flipside, it is 3 dimentional (I
built mine standing on top of a stepladder. Tunning can also be a
chore. A three element would have been easier to tweak.
cheers

Ah, yes! Back to first-year EE in undergrad school . . .

Did it exactly that way, Peter, as a homework problem in fact. One of the first "real" applications of the "new" differential calculus that we were busy learning.

Just one comment to Jerry:

In all fairness, you should not address the newsgroup with a problem and literally demand a detailed response - to the point of insulting one of the respondees - without having presented at least some evidence of having done your own work first.
A brief overview of what you failed to comprehend would have given everyone a better set of clues as to how and at what level to respond. Merely naming something that you failed to understand upon first encountering it is not sufficient.

As several have taken their time to explain (and which Walt Maxwell does very well indeed in his book that you failed to finish, far beyond merely "mentioning" it), the concept is both childishly simple and devilishly complex, depending upon where and how it is applied and examined. While Peter made a workmanlike stab at conveying the gist of the matter, I suspect that even at that level of detail, you may still be somewhat in the dark about how it all applies to antennas, etc. That is what Maxwell tells you in his book . . .

You will find enormous talent and expertise among this group which is yours for the asking. But, learn to "ask nice" with reasonable questions and you will get more and better responses. Insulting those who respond is not the way to go . . .

> extraction of maximum power from the transmitter.

Wow! Then, by definition the load resistance equals the internal resistance of the transmitter and the maximum efficiency of power transfer to the load is 50%.

Somehow, I don't think you meant to say that . . .

Seems to me that a more correct and useful statement would be that when the transmitter is presented with the resistive load for which it was designed, it will deliver its rated power at specified distortion levels and with specified efficiency and heat loading, etc.

My Icom IC-756PRO produces 100 watts r-f output; I strongly doubt that the finals are being presented with 200 watts of d-c input power, or else that little fan would run a lot harder! <:}

and have elected themselves the internet police, they need to
>lighten up. I sold my TriEx Tower to a ham in Rhode Island who was
>only too happy to pick it up. A ham trucker from 7 land is considering

Im Not internet police but this group is for discussion of antennas,
Radio forsale is down the hall. Any common sense tells you that a
world wide group and Posting a Pickup only doenst make good judgement.
We used to have a forsale@local and A @ww on PBBS;s too but everyone
used every one they could spam. Now they are gone.

I used to belong to a discussion group here on usnet about another
subject that also had a forsale. People like you got upset because
they could post in both, even though it violated the charters. Other
got upset that we wouldnt leave it alone as it was only one or two,
and who were we net cops to tell them not too.. Then one or two became
10 or 20 then 50 lor 100.

Guess what, Now there is 2 Forsale groups and No discussion group.

The Ive gotta sell it no matter whats won. The I would like to only
discuss it lost.

Guess Rec.radio.amateur groups will all go that way now as I see more
more adds posted to all groups.

After all its only a few right now.

Good luck, Just cause ya;ll think Im a net nut, Ill unsubscribe and
let you sell your wares on the discussion group. but if you come in
here some day and ask a question and all you get is FOR SALE Ads,
Dont say I didnt warn ya.

==========

Paul, I have been thinking along the same lines myself. If the soil resistivity is 377 ohm-metres then a radio wave arriving at the surface from any angle is simply absorbed 100 percent and lost for ever.

Maximum absorbtion minimises the power available for the antenna to radiate upwards. At any other value of soil resistivity some of the power will be reflected back into the heavens. Only at zero ohms (salt water?) will all power be reflected up from the soil surface. At infinite ohms the soil permittivity will reflect some power upwards but it is debatable whether the power which goes downwards is a power loss or not.

The above might apply to a horizontal dipole which is not in contact with the soil. But suppose we have a simple 1/4-wave vertical above a few radial wires.

We now find the radiation resistance changes as the soil resistivity increases and the distribution of the current in the ground changes. Much depends on the length of the radials.

But intuitively, if everything else except radiation resistance and soil resistance remains constant, there MUST be some value of soil resistivity at which the losses are a maximum and efficiency is a minimum.

I began thinking along these lines as a means of testing the accuracy of antenna modelling programs which take soil characteristics into account. But right now the subject won't bear thinking about. I give up!

Reg, G4FGQ

Yup, they hit many from 5000 feet, but they work.
We have a lot of short towers around here. They started out with them
running up around 300 feet or slightly less. Now that the area is filling in
the height is getting a lot shorter.

I forgot to turn mine off and I received a call at over 5000. That reminded
me to turn it off.

728. Re: Just a comment on losses in the ground.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-11 08:46:28 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C3EA664.AD041D@eznec.com>
Source record: 151116

It doesn't quite work like this. A plane wave is completely absorbed only if the soil's intrinsic impedance is 377 + j0. This is quite different from saying that the soil's resistivity is 377 ohm-meters. The intrinsic impedance is given by:

sqrt(j*omega*mu / (sigma + j*omega*epsilon))

where omega = 2*pi*frequency
sigma = soil conductivity in siemens/m
epsilon = soil permittivity = epsilon0 * relative permittivity
mu = soil permeability = mu0 for non-magnetic material

If you play with various values for the soil, you quickly find that the only way you can get 377 + j0 is by setting the soil conductivity to zero and the relative permittivity to 1. Then, of course, it's the same as air, and has the same intrinsic impedance of 1.

In the case of ground systems, there is indeed a combination of conductivity and permittivity that gives the highest ground system loss. But it's not only a function of the ground constants -- it's also a function of the radial length. If the change in ground constants increases the effective radial length to make the radials nearly a half electrical wavelength long, the loss can increase simply due to the increased effective radial length. So you can correctly say that for a given antenna, radial system, frequency, and soil permittivity, there's a soil resistivity that maximizes ground loss. But trying to simplify it further is likely to lead to wrong answers.

Anyone interested in knowing the intrinsic impedance the ground can easily get it from EZNEC v. 3.0, even the demo version. In the main window, just click Utilities/Ground Info. (You have to have Real ground specified for the Ground Type.) This window also gives the velocity factor, skin depth, complex relative permittivity, and complex propagation constant for the first ground medium.

>Somehow, I don't think you meant to say that . . .

This is the perenial problem with this topic, inevitably the basis of
match is shifted away from the Conjugate Match to the Zo Match by the
careless addition of "efficiency" to the discussion of conjugation.

>
>Seems to me that a more correct and useful statement would be that when the

This is undoubtedly the exact expression found in the specification
for any transmitter's Output Z. It is for my Drake and Kenwood HF
rigs.

>
>My Icom IC-756PRO produces 100 watts r-f output; I strongly doubt that the

>
>72/73/oo, George W5YR - the Yellow Rose of Texas

Hi George,

Missing? It is a simple matter to take the input current and multiply
by the input voltage. Both my rigs require a 20+ Ampere supply.
receive
5 A * 13.6 V = 68 W
transmit 100W
20 A * 13.6 V = 272 W

...or thereabouts.

The garden variety HF SSB rig has a push-pull, class AB amplifier at the output that is the major sink for that 20A from the supply.

What about your own? Are your finals running on less than 10A? What does Icom specify for DC Input?

No question, a good receiver would be a solution. However my intention is,
that everyone of the twelve participants can receive that channel using
a standard stereo equipment.

If a source has a fixed impedance and open circuit output voltage(*), then a load having an impedance equal to the complex conjugate of the source impedance will receive more power than a load of any other impedance.

You can take that to the bank.

But what does this have to do with transmitters and antennas? Not much.

==========
Using one of the more advanced NEC programs, what is the soil resistivity
which give lowest radiating efficiency for a simple 1/4-wave antenna with
one 1/4-wave radial, near or on-the-surface ?

To keep things very simple, while varying soil resistivity assume soil
permittivity is unity or some convenient fixed value.

George, W5YR wrote:
"Then, by definition the load resistance equals the internal resistance of the transmitter and the maximum efficiency of power transfer to the load is 50%."

That would be true were not some of the internal resistance of the transmitter "dissipationless resistance".

An open switch has infinite resistance and zero dissipation.

Most of a transmitter`s output resistance comes from open-switch time.

Source record: 151025

I am in the process of erecting a 2-element 5-band quad. The loops were all premeasured and I will go with these measurements. I am using a coax switch (mounted on the boom) to switch one feed coax to the desired element. Using a Yaesu 450 rotator. Tower is 40 feet. Total feed length (to switch) is 150'.

At the moment, the quad is tied to the tower with the bottom loop less than a foot above ground. Everything seems to load and switch OK, although the SWR on 15m is higher than I would like (2:1). This may be due to the location (at ground level).

This is my first quad. If you have not played with one before, be prepared for a hassle in handling the thing. As several people have said, it is a three dimensional beast and can be quite awkward to move, erect, position, and so forth. In theory, it is less than 50 pounds (including coax, switch, an 8' aluminum mast, and so forth). However, 50 pounds in the awkward shape of a quad is messy for one person to handle. A Yagi is definitely easier to this respect.

I decided on a quad for the usual reasons: low tower, 5 bands, smaller rotator, possibly less "atmospheric noise", better bandwidth, etc.

Pooth!

How eager are You at doing this?

It of course CAN be done.
Go to the library. Search in Radio handbooks,
for example the ARRL VHF Handbook on the subject "cavity
filters"

(Leben Sie mi¿½glichen innerhalb Deutshlands? Ich glaube
dass es auch in den "Antennehandbuch" von Karl Rothammel
behandelt ist.. Publiziert auf der Militi¿½rverlags DDR,
aber trotzdem sehr gut!)

Make a cavity filter for 94.3. Not expensive, if You plan
on having it inside You house (equal temperature) but MUCH
work!

Best wishes/Vielen glueck!
V.

744. Assembling a Wire Mesh Dish for Radio Astronomy

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-11 16:49:53 UTC
From: Wayne Watson <mtnviews@earthlink.net>
Message-ID: <3C3F17E8.5F4BF4EC@earthlink.net>
Source record: 151032

I'm finally getting around to reassembling a dish for radio astronomy purposes that I acquired a few
years back. It's 10 feet in diameter and has radial spokes with screen-like (mesh) metal sectors
between the spokes. The mesh is inserted into slots on either side of the spokes. I'd say so far
this is not an easy process. At the moment, the dish is broken into about six sections with 2-3
spokes per section. Maybe I need to disassemble every section and treat this as though I'm starting
from scratch. Then on the other hand, maybe there's a tool that helps make the inserts of the mesh
into the spokes. Maybe it's really a two person effort. Any suggestions? In the mean time, it's back
to my giant puzzle.

(I called a sat dish store in the area and asked them. The fellow knew of the dish design and
politely suggested that I get another dish with a petal design. Maybe he's right.)

The polarization of the wave does not change within the cycle. From the
perspective of an observer at a fixed point, the E-field vector rotates in a
circle as a function of time. At the fixed point, the position of the
E-field vector changes within the cycle.

>

In an ideal line of sight link, yes.

From a practical standpoint, ideal conditions do not exist. In many (most)
cases, the direct line of sight path does not exist. The communications
link is established only as a result of a number of reflected (multipath)
signals arriving at the receiver. In most cases, these reflected signals
will have undergone some level of polarization distortion (rotation, change
of sense, etc). At the horizontal receiver, there may be a number of
signals that are vertically polarized, horizontally polarized or more
likely, signals that are somewhere in between.

While multipath fading can be a problem in a communications link, many times it is only the multipath signals that allow the communications link to be established.

The key to easily sliding the screen panels into the grooves on dishes
like you describe is that everything needs to be in like new condition.
The tiniest little dings in the edge of the mesh or improper spacing of
the ribs will make it a nightmare.
I agree with the dish guy...or even buy a good used dish from
somebody...you can often find them free for the asking.

Source record: 151035

Hello Frank,

Computer modeling/optimization of Yagis and Quads have provided a great amount of information about their performance capabilities. Despite what some claim, the performance differences between well designed, properly tuned Yagis and Quads is small. W4RNL has investigated many configurations of both types of antennas. His results are available at:

http://www.cebik.com/radio.html

Gain, VSWR and pattern (front-to-back) across the band depend more on the individual antenna design rather than whether it is a Quad or a Yagi.

The Quad offers a slight advantage in achievable gain since a horizontally polarized Quad performs similar to two Yagis stacked 1/4 wave apart. The difference is negligible, only about 1 dB for two element, short boom antennas and even less as the boom length gets longer. It is possible to switch between vertical and horizontal polarizations on a Quad (although few implement this capability). The Quad is also less prone to corona discharge and may be more quiet on receive at certain times. If your tower is guyed, the Quad requires more clearance above the top set of guys than a Yagi.

The Yagi (2-D) is easier to handle during installation than the Quad (3-D). Typical Yagis are generally more rugged than Quads although either can be mechanically designed to the same level of wind/ice survival.

Since Quads and Yagis give about the same performance, you should consider factors such as cost and mechanical issues (wind/ice survival, rotor/mast/tower requirements, ease of installation and maintenance) to make your decision.

By the way, others have posted several Quad versus Yagi performance claims that are incomplete generalizations. Many fail to realize antenna height, siting (terrain and surroundings) and propagation conditions can produce drastic differences in signal level. These parameters often show far more variance when 'comparing antennas' than the actual differences between well design Quads and Yagis.

Good luck - I'm sure whatever you install will be a
significant improvement over the R-7!

The tower is 600 feet high on top of a similarly endowed hill. I can put the antenna anywhere I want, but I'd probably limit it to between 100 and 300 foot levels. The building (well, where the equipment will be installed) is about 200 feet away (that's about 500 feet of coax). There will be other antennas on the tower, so icing will be a problem, as will falling ice from above. I need enough gain to offset the coax loss. Anything smaller than 1/2 inch is too lossy at 450MHz. Naturally, Andrews 7/8 would be nice, but 500 feet will cost me about $2k. I would consider LMR 500 or 600 or even 900.

I'm worried that the Diamond F718A just won't handle the harsh environment, so I've looked into a Celwave PD455 or PD458. These sell for $996 and $1250. Getting pricy. Compared to a Diamond for $200, which also has more gain than the Celwave models, I'd rather save the money. But I won't be able to change the antenna every few months if it can't stand up to the elements.

That's where I am at the present time. I wish I had a money tree, or some donations of coax and/or an antenna !

Cavity filters reduce the signal level.

There are two ways to do it. The first is to make a cavity that peaks the desired signal (94.3 MHz in this case). This would be a pass filter. Unfortunately, these generally are not very sharp, so might not do a good job of minimizing the undesired signals.

The second way is to make two cavities that are notch filters. These can be made quite sharp. The two notches would be at 94.0 and 94.7. There would be some signal reduction at 94.3 - but an amplifier could always be used to regain the signal level. The noise floor might also increase.

Source record: 151052

Hi Group,

I would like to put a 20m, 15m and 10m dipole on one coax line.
The 20m would form a vee, the 15m would be a hoz dipole and the 10m
would form an inverted vee.

I used the standard formula for each dipole lenght and put the data into NEC.
The VSWR plot(s) for the multiband antenna was no where near what I was
expecting. I when back and examined each dipole without the others to verify
the results were as expected.

I understand that adding extra dipoles to a single line feed will change the
resonant of the other dipoles. So, I was looking to find someone who has done a
similar concept and what dimensions were used.

How about a 40meter and 20meter dipole(s) at which same feed and using the
40meter as a 15meter antenna?

Thanks,

Paul

765. Multi-Band Dipole and 300 Ohm Feedline ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-12 03:16:10 UTC
From: milo17@aol.com
Message-ID: <20020111221610.28555.00000855@mb-mp.aol.com>
Source record: 151053

Hello group,
I am currently using a 40 meter dipole fed with 50 ohm coax for
40/15 meters.My question is : would it be possible to feed this antenna with TV
300 ohm line, through a tuner to obtain multi-band operation ? If so, would the
feedline radiate at all ? Would efficiency be better or worse ? My concern is
Noise both to and from my transceiver. I picked up S9 noise level from my
television on 15 meters with an indoor dipole. I will be using a FT-817, 5
watts out to an outdoor dipole.
Any help is greatly appreciated !

Thanks to the group ,
Mike N2JVT

As a rule of thumb, dipoles seem to want to be shortened a bit in this
configuration. I've seen a number like 454/Mc tossed out as being
typical but given the obvious variations possible, anything might go.
In practice, using a 40 dipole on 15 generally works ok but that
evaluation may be affected by how critical you are about the SWR.
Wanting a 40 SSB dipole to be good on 15 CW might be a cruddy match
whereas 40 CW/15 SSB might be ideal.
Having both a 40 and a 15 on the same feedline will certainly make 15
difficult to trim.

Here's another idea. Put up a 32ft dipole fed with 300 ohm ladder-line. A feedline length of about 49ft will get you on 15m and 10m. Add another 8ft to 57ft and you can hit 20m. If you're lucky, you won't even need a tuner. Make it 59ft for 17m and 56ft for 12m.

I run a 32ft rotatable dipole fed with 300 ohm ladder-line. I vary the length of my feedline and don't need a tuner on 20m-10m.

Check out the No tuner shorty HF dipole on my web page. It is a 40m dipole
fed with ladder-line and requires no tuner if one varies the length of
the ladder-line for a near-perfect match on all bands 40m-10m.

Mike,
Can you feed your antenna with 300 ohm twin lead? Yes. Would there be any benefit? Not really. Would it be more efficient? No. Would the feedline radiate? It could, but it isn't a sure thing. On the whole would it do you any good? Probably not. If your getting noise from your TV because of the antenna being in side, you would still have the same problem, proximity. Go ahead and use an outdoor antenna with the coaxial feed line.
'Doc

I have been doing this foy years with 40 and 80 meter dipoles in
parallel. I have also added 20 and 30 Meter legs to the parallel
dipoles. Seperate the ends as far as possible. Run the 80M in one
direction and the 40M in another. I have always had to do some trimming
after I put them up.

Sure, it will work. The feedline won't radiate too much as long as you
have the antenna balanced. If you get noise on a coax fed dipole, you
will with the tv line fed antenna also. About all you can do is turn
the tv off or fix the tv.
Efficiency on 40m will be slightly worse due to the tuner losses. But
it won't be too drastic as long as you use the least inductance with
the tuner. It's worth it to be able to work all bands. You couldn't do
that with coax and not have large losses on some bands. I have a tv
line fed 40m dipole in my attic as a standby/storm antenna. MK

Did you change the source to match the elements driven, or use a
common short line to connect all the elements together? There are two
ways to model that. Place the dipoles at slightly different heights,
and change the source to match the band driven, or you can make a very
short wire to connect all the elements together and use one source
that is placed in the center of the short connector wire.
>

If you place the antennas at right angles , you will have no
interaction to speak of. If in the same plane, try to spread apart as
far as possible.
>

Greetings,

I'd like to thank all of you who visted the website(http://www.sauderelectronics.com) and ordered, what great support the online community has shown for the site and its products. To answer many of you: Yes, the prices on the items are not introductory, they will remain the same as long as our customers(you) continue your great support. I'd specifically like to thank Frank Leaf who was extremely helpful in our online endeavor and volunteered to help with website improvements.

So, with no further ado, I announce our January USENET only specials! These specials are not posted anywhere else(except the website) and were designed for everyone who has supported our effort thus far:

1. Pack of 10 Silver Teflon PL259s for ONLY $8.00!
2. SMA Adaptors, mix and match, 3 for ONLY $10.00!
3. UHF SO239 3" Mag Mount, $2.00 off the regular price of $15.00 for ONLY $13.00!
4. Any order over $25.00 receives a special mystery gift FREE!

Order now at http://www.sauderelectronics.com

Thanks, and 73's

It will work fine Mike, but if you live in an area where you get alot of
rain, you may want ot consider 450 ohm line or 600 ohm line. the 300 ohm
stuff can become quite lossy when wet.

There are Comercially made mounts you can buy.. What length of Vertical are
you planning? the taller the more depth you will need.. I've had good
sucess diging a hole with a post hole digger and sinking a 1-1/2 inch pipe
about 3 to four feet deep for regular trap verticals. When I had my 80
footer up I used a pipe welded to an old tire rim and burried about 5 feet
deep but that was a guyed antenna.

anyway a web search on vertical mounts should give you some ideas of what
available.

Message-ID: <TYW%7.6405$kt2.1166335139@newssvr15.news.prodigy.com>
Source record: 150970

GW, thanks for the example. Are you a teacher? I had understood conjungate matching, (to a point). Other writers didn t call it conjugate matching. There are some other writers out there who say you have to cut your dipole to get an exact 1:1 SWR; that you have to have your transmatch at the antenna; and that all power reflected back to the line is lost. From Maxwell's statement, it would seem one could use a "random length" dipole cut to a length for the lowest frequency in use and use a near lossless line like ladder line or open wire line, and an antenna tuner and you would have an "all" band antenna.

It would be nice to have just one dipole out there instead of the four that I have for 12,17,20, and 40.(and 15 using the 40 meter dipole) If I understand Maxwell, I could use a 40 meter dipole and use it on 40,30,20,17,15 and 12 meters if I have a near lossless line and, proper matching. Since SWR really doesn t matter since power is eventually reflected back to the load anyway, minus any attenuation on the line. (?)

It would seem like there would be practical limitations, if that were true. I did however, get out on my Butternut HV6X on 17 meter with my tuner getting SWR down to 1.4:1. 12 meter was another story. But in this solar cycle anything is possible and even an inefficient antenna can get out.

Roy asked -

> What frequency?
>
==========

Roy, you are being humorous but mostly evasive. In the time taken to think about it and ask your question you could have done the job and provided an estimate of soil conductivity everybody is eagerly waiting for.

Just enter ground permittivity = unity and set a frequency at which the vertical is approximately the required 1/4-wavelength.

Then vary ground conductivity in a few very crude steps between sea water and Sahara sand. Simple!

If you can't find a conductivity which minimises radiating efficiency then the program's modelling performance is deficient.

Regards, Reg, G4FGQ

Go to your local lumber yard and purchase a chain link fence galvanized
fence post.

Pound it into the ground with a big hammer.

Leave about 1 foot sticking out.

Clamp your antenna to the exposed stump.

This also helps out as it functions as a ground rod.

Add additional ground rods if you want.

Don't forget to add your favorite number of radials.

>Are there better techniques? Any suggestions?

In ground that is not stony, you can drill the pipe into the ground by cutting two large teeth in the bottom, and using a mast clamp to attach a cross-bar to turn it. This is much more controlled than the sledgehammer method. Use a level to make sure the pipe is going in exactly vertical.

Choose the largest pipe that the vertical's clamps will fit over, with a heavy wall - in other words, real water pipe and not electrical conduit or anything like that.

A little water in the bottom of the borehole will help ease the pipe down, but not too much because you don't want to soften the ground. Pull the pipe out after every few inches and clear out the plug of earth. Take care not to rock the pipe sideways because that will open out the top of the hole.

For a light vertical up to about 30ft, you need to go down about 3ft in solid clay, or maybe more in very soft earth or sand.

Better still, use a slightly smaller pipe to drill the borehole (light conduit or even rigid plastic is OK for this) and then you'll find that the full-size pipe will tap in easily with the sledgehammer, firming up the earth around it.

If the top of the borehole is not a tight fit on the pipe, or if the pipe starts to open up the hole when the vertical moves around in the wind, dig out about 1ft square by 6in deep around the top of the pipe and fill it with concrete to spread the load at ground level.

Obviously this method is only suitable for light verticals, but it works very well in the right kind of soil.

An antenna tuner (transmatch) achieves a system Z0-match and re-routes
virtually all the reflected power back toward the antenna. You can have
the case where the transmitter is putting out 100 watts and the antenna
is radiating nearly all of that 100 watts while the SWR is 5.8:1. I
chose that SWR as an example because the forward power would be 200 watts
and the reflected power would be 100 watts, i.e. half the power is
reflected back from the antenna. But the tuner re-routes it right back
toward the antenna.

I have just such an antenna on my web page. It's called the 'shorty' version.

> It would seem like there would be practical limitations, if that were true.

The practical limitation is that coax is too lossy to handle very high
SWRs so you are forced to go to ladder-line or open-wire line.

There might be a benefit and it might be more efficient. With 300 ohm line, the necessity for a good match at the antenna disappears. In other words, for any given SWR, the 300 ohm line will be less lossy (when it is dry) than ordinary coax.

For instance, using EZNEC, a 66ft dipole resonant on 40m has a feedpoint impedance causing an 8:1 SWR on 50 ohm coax on 15m. Those conditions can cause excess losses. However, the 300 ohm line with an SWR of 4:1 exhibits negligible losses working into that same 96-j164 ohm impedance.

What I do is use a post hole digger to sink a 2x4 a few feet into
the ground. Then I attach the aluminum tubing to the 2x4 using
U-bolts with a piece of PVC around the aluminum tubing for
insulation. For very heavy antennas, I use two 2x4's in a
4x4 configuration using treated lumber, of course.

Jerry - You got it! Only I would suggest you not choose a 40 meter dipole to start with. On the even harmonics, it will be harder to match. It is better to not be resonant on any frequency than to fight the even harmonics. The antenna "should" be at least 3/8 wavelength on the lowest frequency you plan to operate. I used 102 feet because I had an old G5RV laying around. It tunes 160-10 meters and gets out well even though it is "short on 160.

Now the problem, if you would call it that, is that the antenna exhibits many lobes on the higher frequencies. Instead of the broadside figure 8 pattern you see with a dipole, the multi band antenna pattern will look more like a four leaf clover and then a daisy as you go up. This could be good if you are lucky enough to have a lobe in the drection you want to work but it is hit or miss and the nulls are steep.

You can fix this problem and even out the pattern by using a top fed inverted L configuration. I have mine with the center at 60 feet. One side is horizontal and the other drops straight down. The antenna is one half horizontal and one half vertical. Hence the inverted L. About 135 feet of ladder line back to the tuner. I think this antenna is superior to a dipole because the coverage is more omni directional. It certainly plays better than my old horizontal G5RV.

I am surprised more hams don't use this configuration. Cebik praises it pretty highly. You can learn more about the top fed inverted L on Cebik's site.

I'll give you the same reply I posted on the thread about conjugate matching.

Why limit yourself to only three bands? Use a tuner and ladder line and work all the bands with one antenna. The antenna "should" be at least 3/8 wavelength on the lowest frequency you plan to operate. I used 102 feet because I had an old G5RV laying around. It tunes 160-10 meters and gets out well even though it is "short on 160.

Now the problem, if you would call it that, is that the antenna exhibits many lobes on the higher frequencies. Instead of the broadside figure 8 pattern you see with a dipole, the multi band antenna pattern will look more like a four leaf clover and then a daisy as you go up. This could be good if you are lucky enough to have a lobe in the drection you want to work but it is hit or miss and the nulls are steep.

You can fix this problem and even out the pattern by using a top fed inverted L configuration. I have mine with the center at 60 feet. One side is horizontal and the other drops straight down. The antenna is one half horizontal and one half vertical. Hence the inverted L. About 135 feet of ladder line back to the tuner.

I think this antenna is superior to a dipole because the coverage is more omni directional. It certainly plays better than my old horizontal G5RV. Your nest of dipoles is going to favor two directions and if the antennas are at right angles to each other, your to be pointing in different directions on each band.

I am surprised more hams don't use the L configuration. Cebik praises it pretty highly. You can learn more about the top fed inverted L on Cebik's site.

This is somewhat of an old wive's tale. What you say is true if you are using coax for the feedline but absolutely not true if you are using ladder-line or open wire line. Here's why:

The feedpoint of a 40m dipole used on 20m is around 6000 ohms according to EZNEC. Assume we feed the dipole with 450 ohm ladder-line. The SWR on the ladder-line will be 6000/450 = 13.33:1. The ladder-line will transform the impedance because of the SWR. If the ladder-line length is made an odd multiple of 1/4WL, then the impedance seen by the transmitter will be 450/13.33 = 33.76 ohms which gives a 50 ohm SWR of 1.5:1 which is ACCEPTABLE EVEN WITHOUT AN ANTENNA TUNER.

Using random lengths of ladder-line, the impedance seen by the transmitter can vary between 34 ohms and 6000 ohms with reactance. If one knows what one is doing, one doesn't have to worry about antenna length as long as the antenna is 1/2WL on the lowest operating frequency. Much too short antennas can result in sky high SWRs even using ladder-line.

Moral: Don't worry about even harmonics in a dipole if you are feeding it with ladder-line or open-wire line.

I would have to disagree with you about 160m. According to EZNEC, a 102
ft. dipole on 160m would have a feedpoint impedance of 5.8-j1474 ohms
and an SWR of 900:1 on the 450 ohm ladder-line at the antenna. Assuming
a matched line loss of 0.05 dB, the losses in the ladder-line would
be about 8 dB. Assuming no tuner losses, only 1/7 of the power
reaches the antenna.

I just read W4RNL's excellent articles about all sorts of antennas. The NEC simulations are outstanding, and give lots of insight into the Yagi/Quad discussions. From what I read, it would appear that a Stacked 2-element Quad has a lot going for it. Here's what I learned:

1) Run Double #14 wire elements, Spaced 5": Adds to the bandwidth, Gain, and F/B ratio.

2) Use a Spider Quad: Provides more optimum spacing of course.

3) Feed each band seperately with 1/4 Wave sections, a remote switch which opens both sides. This reduces the intercoupling of the "other bands" and provides cleaner patterns.

4) Seperate the Two 2-element Quads by 30', center to center, feed them In-Phase (of course). W4RNL studied vertical stacking, but I'm thinking horizontal "stacking" would be easier to implement with a single rotator, on a typical tower, and provide a balanced height.

W4RNL's analysis was getting an additional 2.1 dBi gain for the second Stacked Quad! Overall, on 20M he was showing 12 or more dB of Gain, and great bandwidth/FB ratios! Am I dreaming here? The multiband 2 element is way easier to tune than a 4 el, and the stacking factors are apparently pretty well known. Should I take down my 4el Quad, redo it with spaced double wire elements, and add a 30' horizontal boom, and convert to dual 2-element configuration? Also I'm thinking I could get a 1 Wave Length 40 meter "Vertical" steerable Loop in there somewhere. I'm not sure my GEM Quad spreaders are up for double wire duty, but there's not much icing here in the Wash. DC area, and with some extra cross bracing, it might work,. Currently my boom is only 25 feet, but with the GEM quad spider configuration, I could cut that in half for the side booms, add a 30' cross boom, and voila! With a crank up/down tower, should stay up if brought down when not in use. If what I read is true, this might be a Poor Man's solution to those Super Rich Guy Stacked Christmas tree Mono-Band Yagi's with 50' booms at 100', with tubular towers that turn I see on DX web sights.

Any Thoughts?

CAM,Thanks for your input. I can see how you can get low SWR's with your setup. Looks like it takes up a lot of room inside though. I would have to settle for a ladder line or open line that might be an odd multiple of 1/4 wave on some frequency, maybe 20 meters. How will that fly on 40, 17, 15, 12, and 10?

I suspect that using a tuner causes losses in the range of 30 %. And with
the upcoming dip in the solar cycle, I need all the output I can get. Tuner
with my Kenwood works, but I hate the on air tuning. And it does not do a
real good job matching. Am using a 901B. It does a respectable job tuning
off line using my Autek Have a 969 on order. Would be very nice not to
have to use a tuner though.

If I were going to install a pipe deep into the ground, I'd do what they do for Telephone Poles for supporting boat docks here in the Annapolis Maryland area. I'd rig up the water hose to the end of a 10' long piece of 1.5" or larger water pipe or better yet Black Gas pipe, and "Jet" it into the ground. If it gets stuck, you'll have to pipe wrench it around, or give it some Sledge hammer action, but will eventually go in without all the "Fan Fare" of driving it in. Use a Step Ladder with some cinder blocks to weight it down to steady the pipe. Cut some teeth in the end so the "wrench around" maneuver is more effective. Put the water on real slow so you end up with a "Snug" hole. This will take all day, but plenty of opportunity to catch the "game" or 6-Pack it. If you're going to use the pipe as a ground rod too, drill 3/16th inch holes in it as it goes in, sealed with a bunch of wraps of Electrical Tape to keep the water pressure going down.. When it's in, let it set a day or two, untill all the water drains out, then pack it tight with Rock Salt, then blow out the electrical tape with a minute or so of full water pressure. Reseat the pipe, disconnect the hose, and for the next few weeks, keep the pipe full of rock salt and topped off with water. Your ground conductivity will increase substantially over the next few weeks. Keep the pipe packed with rock salt and topped off. When you have a ring of dead grass 6' or so around the pipe, you might want to consider annual treatments instead of monthly!

Of course I don't Condone Ground Counterpoised Verticals, but if you're into it this is "The Way".

My setup takes up no room inside. I have knife switches mounted on a
piece of plexiglas installed in the window of my hamshack. With those
knife switches, I switch in/out loops of ladder-line that are mounted
on the outside of the window. You can ascertain everything I am doing
by downloading and using the free demo version of EZNEC from eznec.com.

It is pretty well known that if the antenna is 1/2WL, the ladder-line
should be close to 1/2WL increments and if the antenna is one wavelength,
the ladder-line should be close to odd multiples of 1/4WL. What is not
so universally understood is that those matching techniques work for
virtually any length of dipole. For an antenna with a feedpoint
impedance of 450+j450 ohms, a 3/8WL matching section works well. And
for 450-j450 ohms, a 1/8WL matching section works well. This is
intuitively obvious to anyone who understands the Smith Chart.

One Last thought: The hardware store has these rubber/hose clamp connections that will seal a bunged up water pipe end. You can rig this up to a water hose fitting, and when the need to Sledge it happens, disconnect the hose clamp, pull off your fitting rig, and wail on it big time. If the pipe end mushrooms too much, cut off the end and keep at it. When you think the pipe is deep enough, just cut if off, and call it done.

805. ANTENNA IDEA!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-12 18:12:35 UTC
From: marvin rosen <raghead@worldnet.att.net>
Message-ID: <n0%%7.254680$WW.13364529@bgtnsc05-news.ops.worldnet.att.net>
Source record: 150992

Would it be practical to have a sloped 65' piece of wire, attached to a vertical 80 mtr loading coil mounted on a piece of pvc pipe on a chimney? This coil would also have a top hat. The bottom end of the wire would go to a tuner & appropriate radials.

806. Re: ANTENNA IDEA!!!

You'll need to draw us a picture, but if you can run a 65' piece of wire in open air, why polute/crap up things with a Loading Coil (AKA Attenuator) and Radials (AKA Attenuator)? I'd check your other options of getting on 80, especially since you have a tuner.

The sloped 65' piece of wire will make a nice 80 meter antenna all by
itself and with a little bit of pruning would give a good 50 ohm match
without a tuner. Consider it as a 'leaning' quarter-wave vertical.

808. Re: Multi-Band Dipole and 300 Ohm Feedline ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-12 19:07:42 UTC
From: Mark Hall <vze2mhvc@bellatlantic.net>
Message-ID: <3C408934.75F84A2B@bellatlantic.net>
Source record: 150995

That TV twin lead crap is marginal in any configuration, I'd go for the heavier duty, wider spaced, 450 ohm vinyl "ladder line" at a minimum. It will last maybe 2 or 3 years and then need replacement. If you could manage a longer dipole section you'd probably be happier. If an 80 meter dipole section is possible, we're talking a serviceable and well behaved antenna then. Noise shouldn't be a problem. But, if you can manage a full wavelength LOOP on 80, fed with that 'Ladder Line" and tuner, 40 meters and above will be more what you want.

Looped and getting Loopier

The Diamond claims over 11db gain. The Celwave models are 8 and 10db. The one that costs more has less gain, so they must be doing something else for $1240.

I'm worried about falling ice and high winds. I'd have no problem with a Diamond at my house, where the environment is much better. Also, getting up 300 feet to replace a busted antenna is not something I will be able to do nor afford too often, hence the harsh environment requirement.

At this point, I've committed to going just UHF on the tower, so this may change the requirements a bit. I don't think any commercial antenna will do multiple ham bands.

Hi Eric,

Twenty meter tuning is determined by the placement of the 30M coil tap on the 40M coil. As per the instruction manual, it may be necessary to move the strap up a turn or down a turn, depending upon where resonance falls in your installation. An MFJ 259B will help determine this. In some instances, it may be necessary to rotate the 30M coil around a partial turn on the 40M coil tap to find the right spot. That should solve the problem.

Good luck and 73,

Ed, W0VC

Mark,
You asked if you were dreaming. Yes, but theres not much wrong with that, just remember not to trip while your walking around! Personally, I think that taking down a 4-el quad to put up two 'stacked' 2-el quads, would be a good 'government' project, or not very practical when you take a look at the mechanical aspects. Not exactly like putting a '48 Packard on top of your tower, maybe more like a '98 Toyota.
I hope someone tries it 'cause I'd really like to see the results. But if I already had the 4-el, I think I'd leave it alone...

let me add something to this....if you were to configure the gadgetry at
the top end in the form of a trap (coil + capacitor) and then extend off
with another 50-60 feet of wire you might have the makings of a decent
80/160 antenna.

Stefan0,
Sure, it will 'work'. But the question is how 'well' will it
work. You can make any very short antenna 'work' with a 'large'
enough matching network. The performance of a very short antenna
isn't always worth the time and effort, though...

It would depend on the bands being used. It might fill in the gaps of
a long dipole on the high bands, but I think the nulls and the
expected bad effects are kind of overstated. By the time you have your
antenna up in the real world with all the reflections and diffraction
in the ionosphere, I think it kind of evens it out a bit compared to a
model. Also unless his dipoles are super high up, the effects of the
nulls on the ends isn't really that drastic either. I worked loads of
stations almost exactly off the ends of dipoles , that still had good
signals. Mainly for the same reasons as the previous. I bet the
overall performance and efficiency of the right angle 1/2 wave dipoles
will be higher than the top fed L in "most" cases. The G5RV wasn't
really a good gauge as a reference. On the lower bands such as 80 and
40 meter close in stuff, I'd rather have the dipoles any day. But like
you say, if fed with coax, you are limited. On the low bands like
160/80 dx, the L would probably be better. I recently had a 20m dipole

up at about 40 ft for SSTV. I noticed no real directivity at all. I had it broadside to the NW/SE, and I still had good results in the opposite directions. Anyway, I like L's for vertical type uses such as low band dx, but for a horizontal wire as a general use antenna, I'd rather have the dipoles. Even if real high up on the high bands. But this can't really be confused with using a long 80m dipole and a tuner on 10m, compared to a normal coax fed 1/2 dipole on 10m. In most cases, the 1/2 wl dipole will work much better. The real problem I've noticed on using a 80m dipole on 10m is the TOA seems to be very high. It models that way also. I think this kills you worse than all the nulls. I tried one camping one time, and it was pathetic on 10m. The antenna acted like a monster cloud warmer, which is not what you want on 10m. I also remember using EDZ's on 20m. You would think it would seem pretty directive, but it didn't really in the real world. It actually seemed to be better in almost all directions. But that may be partly the dreaded appellation effects at work. :/ MK

822. 160 meter antenna recommendations

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-12 21:30:38 UTC
From: AB2HR <ab2hr@arrl.net>
Message-ID: <lda14ugfoip0fa453kc0mn3fof96tj2q01@4ax.com>
Source record: 151007

Hey folks, live in a suburban area, and am interested in
working 160 meters. I don't have any covenants or restrictions to
work around, but the size of my lot is typically suburban. I have
access to my lot and the lot next door to me. I'm interesting in
hearing what might work as far as a 160 meter antenna. I've been
playing with the idea of mounting a 45 foot vertical (with capacitance
hat to complete the 1/4 wave vertical) on my garage roof (about 8-10
feet high). From there, I'm looking at four relatively heavy ground
wires forming a ground plane from the roof and attaching to a ground
"web" (would run as many and as long smaller gage copper wires as
needed) to the ground.
Obviously, a 45 foot vertical mast would need guying, and
that's just one of the downsides. I live in an older 2-story house,
the length of which is possibly 70-80 feet long... Would it be out of
line to think that a bent dipole along the roof of the house might
work? We're talking older (100+ years) woodframe construction here,
the only detuning factors I can think of are the rain gutters and the
45 foot mast holding up my Windom at one end of the house.
Ideas folks? Would really like to play on 160, but right now,
don't have the antenna for it. Would like some ideas on something to
homebrew...

Thanks in advance!

Hi,
I'm trying to locate some 500 ohm non-inductive termination resistors. The recipient wants 2 watt or 1 watt units, and I'm having no luck locally. He says "film" resistors are a problem, and one question is if carbon-film resistors are a problem, or is he conflating them with metal film resistors?

Ohmite OY series seem as if they might do, being ceramic composition resistors, but they're not listed as being non-inductive.

I need these by the first days of February, and would like to have as many as 5. Any suggestions about what will work, and where I can find them?

The carbon film resistors that I have dug into are typically only 3-5
'turns' of carbon. If it were a VHF circuit that might be a concern but
I don't think that inductance would be a bother at HF.

828. Re: Just a comment on losses in the ground.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-12 22:04:38 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a1qdu9$slcpn$1@ID-124126.news.dfncis.de>
Source record: 151015

Conductivity at which loss is a maximum may very well be a function of frequency. But who cares? Nobody is interested in that. Conductivity is the independent variable in this investigation and the frequency is fixed.

Frequency is that at which the vertical is 1/4-wavelength in height. The single shallow-buried radial is also 1/4-wavelength in length. What could be more simple ?

Suggested values -
Vertical height = 20 metres.
Radial length = 20 metres.
Frequency = 3.75 MHz.
Soil Permittivity = 1.0
Vary conductivity from sea water to Sahara desert to find value at which efficiency is lowest.

Regards, Reg G4FGQ

AMATEUR RADIO NEWSLINE(tm) REPORT #1274 - January 11 2002

Amateur Radio Newsline report number 1274 with a release date of
Friday, January 11th 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T. No more taxicab Q-R-M plaguing a popular ham satellite and lots of FCC enforcement actions highlight this weeks Amateur Radio Newsline report number 1274 coming your way right now.

(Billboard Cart Here)

**

HAM RADIO IN SPACE: TAXI TO SATELLITE QRM ENDED

Some good news for satellite operators. Thanks to some hard work by the International Amateur Radio Union, the troublesome F-M signals to ham satellites from Mexican taxi cabs are for the most part gone. Amateur Radio Newsline's Norm Seeley, KI7UP, has the details:

--

According to the IARU Monitoring System newsletter it now appears that FM radio transmissions from the taxi drivers in the cities of San Luis and Sonora, Mexico area are no longer getting into the 2-meter uplink of the UOSAT 14 ham satellite.

The issue was raised by many involved in ham radio satellite communications including Ray Soifer, W2RS, of AMSAT North America. The newsletter says that it was Soifers plea to the VHF and Satellite Committee at the 2001 IARU Region 2 Conference in Guatemala City generated extra interest and concern about this and similar problems. This lead to some very productive discussions between the Mexican telecommunications administration and the Federación Mexicana de Radio Experimentadores which is Mexicos national Amateur Radio society.

Credit also is given to Alejandro Pereida, XE2BSS, for his thorough technical analysis of the problem and for his persistence in pursuing the matter from beginning to end. The end being the removal of the interfereing signals from the UOSAT 14 two meter uplink passband.

For the Amateur Radio Newsline, I'm Norm Seeley, KI7UP, not far from the U.S. - Mexico border in Scottsdale Arizona.

--

The newsletter reports that after a lot of correspondence and negotiations on this issue took place over the past eighteen months. It also credits Lorne Libin, XE1V, as being an important mediator during this period. (AMSAT)

**

HAM RADIO AND THE LAW: NEW HAMPSHIRE HAM WINS ANTENNA CASE

Meantime, a lot closer to the ground, the ARRL Letter reports that a New Hampshire ham appears to have won a battle to erect an antenna support structure on his property. But says the League, it remains to be seen, however, whether Jerry Muller, K0TV, of Hudson will be allowed to erect the extensive system of three towers that he'd originally planned.

Unlike many amateur antenna battles, this case did not pit Muller against the town. In December 1998, Muller applied for a permit to erect three 100-foot antenna structures on his property, and the town of Hudson granted the permit. Three of Muller's neighbors appealed the grant of the permit, but the Hudson Zoning Board affirmed the grant. The neighbors then sued the town and won, resulting in the order for Muller to dismantle the towers.

Now, in a 4-0 vote, with one justice abstaining, the Supreme Court of New Hampshire has reversed a lower court ruling but it is not a 100% victory. Writing for the court, New Hampshire Chief Justice David A. Brock concluded that the lower court's order requiring Muller to dismantle his towers violated the limited federal preemption known as PRB-1 as well as New Hampshire's statutory codification of PRB-1. However Brock also agreed with the lower court that Muller's three-tower installation did not qualify as a "customary, incidental and subordinate" accessory use permitted by Hudson's ordinance.

While another amateur in Hudson has a tower at the same height, there are no instances of three such towers on the same property. Nevertheless, Brock said that Muller's installation may be permitted within the framework of PRB-1, if Muller can demonstrate that his three towers are necessary to "reasonably accommodate" his communications needs. (ARRL)

**

THE WAR: 73’S GREEN SAYS US COMMUNICATIONS ILL PREPARED FOR TERROR ATTACKS

73 Magazine El Supremo Wayne Green, W2NSD -- thats his title not ours. El Supremo Green says that the United States is ill prepared to handle communications in the event of another terror attack. Writing in his Never Say Die editorial column, Green says that no matter how the terrorist network hits us, the one thing we are going to need is communications. And this says Green, this is another item that the government has been lax in providing.

Green notes that anytime there is an emergency, the first things to disappear are electric power and telephone service. This includes cellular as well as wired phones. He notes that police, fire, rescue and other services have no way to inter-communicate until ham radio operators arrive on the scene. He says that if ham radio is going to be called on to provide services anywhere and at any time, then we need at least 600,000 licensed hams trained and ready to help, and not just the 100,000 or so that are now really active.

Green’s comments begin on page four of the January issue of 73 Magazine. (73 Magazine)

**

THE WAR: PIRATE HAM OPERATION FROM AFGHANISTAN

You may find this hard to believe, but even with a war going on some joker is pirating the YA5T call-sign and pretending to be on the air from war-torn Afghanistan.

According to Peter Casier, ON6TT, and the Radio Society of Great Britain all the operators who had previously put YA5T on the air have left Afghanistan. Casier tells the RSGB that he expects to travel back to Islamabad on the 20th of January and then to Kabul within the following few days. Until then, any station you work claiming to be on the air from Afghanistan is most probably somewhere else in the world.

We will have more D-X news later on in this weeks newscast. (RSGB)

**

BREAK 1

This is ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, heard on bulletin stations around the world, including the Condor Connection repeater intertie thanks to KC6SFP and heard throughout the South-Western United States.

(5 Sec Pause Here)

**
FCC: THE VANITY CALL SIGN PROGRAM MAY RESUME SHORTLY

Some god news for hams waiting for vanity call signs. According to an ARRL bulletin, the vanity program which was put on hold since October 14th as the result of the post 9-1-1 Anthrax mail scare may could be in operation shortly.

The vanity gridlock got started after mail received between October 15th and November 1st was diverted from the FCC's Gettysburg, Pennsylvania, office for decontamination in the Washington, DC, area. That mail, believed to contain more than 100 vanity applications filed on paper, has not been returned to Gettysburg.

Current FCC policy says that paper and electronic vanity applications get equal processing priority, so the Commission halted vanity processing altogether until it could resolve the mail snafu.

FCC staffers in Gettysburg have been attempting to work around the roadblock. Using vanity fee payment data from the FCC's fiscal agent, Mellon Bank in Pittsburgh, the FCC's Wireless Telecommunications Bureau in Gettysburg has been contacting applicants directly to have them resubmit their applications. The FCC now is asking applicants whose paper vanity filings may have arrived at Mellon Bank between October 15th and November 1st and who have not been contacted to get in touch with the FCC to find out if they need to forward a copy or facsimile of their original paperwork. The request affects only vanity applicants who filed on paper and not electronic filers.

More information on whats happening in the ham radio vanity call sign program can be found at the ARRL Website. Its in cyberspace at www.arrl.org under W1AW

Bulletins for the year 2002.

And late word in. The FCC has begun processing some vanity call signs as this newscast is prepared. (ARRL)

**

ENFORCEMENT: EX-KV4FZ'S NEW LICENSE APPLICATION DESIGNATED FOR HEARING

I'm Bill Pasternak, WA6ITF. The FCC has designated a new ham radio license application filed by Herbert L. Schoenbohm, the ex-KV4FZ, for a public hearing. According to the order released on January 9th, the hearing will determine whether Schoenbohm possesses the requisite character qualifications to be a Commission licensee. Schoenbohm lost a series of appeals during the 1990's and was ordered off the air last year. He was given twenty days to request that the hearing on his new application be held. If he fails to do so, his application will be dismissed. More on this story, next week. (FCC)

**

ENFORCEMENT: YOU CANT SEND FELONY COMPLAINT AFFIDAVITS TO OTHER HAMS

The FCC wants to hear immediately from any ham who receives notification that a felony complaint has been lodged against him or her by Glen Baxter, K1MAN. This after the government tells the Belgrade Lake Maine operator to stop sending other radio operators so-called Standard Felony Complaint Affidavits. Speaking on his Rain Enforcement Log, FCC Special Counsel for Amateur Radio Enforcement Riley Hollingsworth says that this is not the first time Baxter has been warned:

--
Hollingsworth: "We reiterated a warning issued by the United States Attorney in Maine to a Belgrade Lakes operator who had sent so-called Felony Complaint Affidavits to licensees who had refused to clear the frequency for his broadcasts, or bulletin shows or whatever they are. Complaints about the nature of the transmissions are also under review as well, and we will be looking at those. That went to Glenn Baxter, K1MAN.

The United States Attorney in that case has warned Baxter that if he continues sending the so-called Felony Complaint Affidavits he may be subject to federal criminal charges for misrepresentation and for using the U.S. Mail to make threats."
--

If you receive one of these Standard Felony Complaint Affidavits, or notification that one has been filed against you please contact Riley Hollingsworth as soon as you can. He can be reached by e-mail to fccham@fcc.gov. (FCC)

**

ENFORCEMENT: FCC - ALLEGEDLY UNCOORDINATED IN CALIFORNIA

Still with enforcement news, the FCC has notified Dean K. Perrins, N6HWI, of Freemont California that his alleged uncoordinated repeater on 443.725 MHz is causing interference to the coordinated K6TWI system. This is a repeater which operates on the same frequency.

The FCC says that it has information that Perrins has been notified several times
regarding the interference problem but that he has not taken any steps to resolve the problem. Perrins was given twenty days from the date of notification to respond to the FCC. (FCC)

**

ENFORCEMENT: FCC - ALLEGEDLY UNCOORDINATED IN FLORIDA

In still another repeater interference case Joseph Bushel Jr., W2DWR, of Live Oak Florida has been directed by the FCC to respond to a complaint that he is operating a repeater on 146.94 MHz after being denied coordination by the Florida Repeater Council. The FCC says that Bushel's repeater is causing interference to the coordinated K4EHM system and the government wants him to explain his actions. The FCC also wants W2DWR to respond to an allegation that he was observed transmitting a digital voice recording an that frequency without ever identifying the transmission. (FCC)

**

ENFORCEMENT: FCC- DON'T TALK ON THAT REPEATER

Meanwhile, another Florida ham identified as Thomas Banks, KB4AN of Port Saint Lucie Florida has been notified by the FCC that he is to refrain from using an area repeater. Specifically, the FCC has told Banks that he is not to be heard over the Saint Lucie Repeater Association's AF4CN machine as requested by the system's trustee. (FCC)

**

AWARDS: ARRL EDUCATOR AWARDS NOMINATIONS SOON CLOSE

According to the American Radio Relay League, nominations close January 31st for League awards that recognize excellence in teaching. The ARRL Instructor of the Year, Educator of the Year and Professional Instructor of the Year awards will be presented, as well as the ARRL Excellence in Recruiting Award. All winners receive engraved plaques. Complete information and nomination forms are available at www.arrl.org. (ARRL)

**

AWARDS: DARA NOMINATIONS TO CLOSE

The nominating period for the 2002 Dayton Hamvention Awards is quickly coming to an end. The deadline for nominations is also January 31st.

There are three awards presented each year. They are the Radio Amateur of the Year, Special Achievement, and Technical Excellence. All amateurs Novice through Extra are eligible.

Awards are decided by the Awards Committee, based partially upon the information received. Magazine articles, newsletters, newspaper clippings, videos and the like are appreciated but cannot be returned.

Nominations can be sent to Post Office Box 964, Dayton Ohio 45401. They can also be filed electronically by completing the e-form on the web at www.hamvention.org. (DARA)

AWARDS: NEWSLINE NAMES FOUR AS SUPER SUPPORTERS

The Amateur Radio Newsline has named four hams who will receive its first Super Supporter Award certificates. Don Wilbanks, KC5MFA, has the names:

--

In alphabetic order, the first certificate goes to Roy Blanchard, N5YHS, right here in New Orleans. It was Blanchard whose assistance made it possible for Amateur Radio Newsline to become a federally tax exempt coropration.

The second is earmarked to Dale Cary, WD0AKO for his decade plus work in putting the Amateur Radio Newsline on the Internet and creating the Amateur Radio Newsline website.

Sandy Donahue, W4RU, receives a Super Supporter certificate for his many years of coordinating the arrival of the Newsline Young Ham of the Year Award in Huntsville Alabama, and the recipients registration at Spacecamp. And for the last several years he has also helped to defray the cost of the mini-banquet held to honor the winners.

Last but by no means least, Todd Hitzeroth, N6ZXJ, was recognized for his years of volunteering with Newsline at its Dayton Hamvention booth and engineering the Ham Radio Town Meetings. What makes his contribution unique is that Hitzeroth lives in California and pays his own way to and from Dayton each year.

With congratulations to all four recipients, I’m Don Wilbanks, KC5MFA.

--

Approval for the creation of the Amateur Radio Newsline Super Supporter certificates and naming of the first four recipients took place at the organizations Board of Directors Meeting held in Glendale California on December 30th 2001. A synopsis of the minutes of that meeting will be posted to our website within the next few weeks. (ARNewsline(tm))

**

INTERNATIONAL-ISRAEL: “FIRST” BRINGS IN NEW HAMS

A new group of radio amateurs has emerged in Israel from a rather unexpected place. According to Hagal International, the new Israeli hams are from an all volunteer Search and Rescue group called First.

First members are on call to provide wilderness rescues in areas such as the Israeli desert and canyons. For communications, First members have long carried two-way hand helds operating in point to point simplex mode. The limitations of simplex in rugged terrain means that there are times when they cannot keep in touch.

Recognizing a need for improved communications, First contacted to Israel Amateur Radio Club to ask if the nationwide repeater system could be made available for search and rescue use. And according to veteran ham radio instructor Moshe Inger, 4Z4PF, when First members learned that they would first have to pass an Israeli ham radio exam, they did not flinch one bit. They studied, passed the test and there are now dozen new hams from Eilat in the South to Golan in the North. (Hagal International)

**

INTERNATIONAL-UK: G3YJO BECOMES SIR MARTIN SWEETING

Meantime, over in the United Kingdom word that Martin Sweeting, G3YJO, on being knighted. Sweeting is the Chief Executive of Surrey Satellite Technology and Director of the Surrey Space Centre. He will join Sir Jimmy Young and Sir Ben Kingsley to collect his Knights Bachelor medal from the Royal Palace. Professor Sir Martin Sweeting, F.R.S., was knighted for his services to the U-K in microsatellite engineering. (RSGB)

**

HAM RADIO IN SPACE: QUIET HOURS FOR AO-40

AMSAT reports that AO-40 satellite ground controllers have begun adjusting the spacecraft's attitude as it enters a period of adverse sun angles. The satellite is currently in a long period during which Earth eclipses the sun near perigee. These periods will continue well into next June. As a result, AO-40's operating schedule has been modified to reflect the decreasing attitude longitude. (AMSAT)

**

HAPPY BIRTHDAY: JOHANNES KEPLER AT AGE 470

VK2KGM notes the 470th recorded birthday of Johannes Kepler last December. Kepler was the first astronomer to determine a mathematical relationship existed that could be used to predict the motion of planets. This became the basis for the Keplerian data we use today for satellite orbits. (AMSAT)

**

DX

In DX, word that F2JD is active from the Philippines as DU1 slash G0SHN on 20, 15 and 10 meters SSB and CW. Listen for him from now until June of this year. QSL as directed on the air. (RSGB)

Three Finnish operators will be active from Tonga through the 15th of January, with an emphasis on 160 to 30 meters. They will work CW, SSB and RTTY with three stations using verticals and dipoles. (Modern DX)

**

THAT FINAL ITEM: FANTASTIC VOYAGE REDUX

And finally this week, the world of medical communications research has finally caught up with the lights of Hollywood. This, as the government approves a tiny radio camera-in-a-capsule that patients can swallow. It is a camera that will transmit pictures to give doctors a close-up view of what is inside of you. Amateur Radio Newsline’s Mert Garlick, N6AWE, has more:

--

The new transmitting video pill is made by Given Imaging Ltd. in Israel. It is called the M2A Swallowable Imaging Capsule. It is also exceeding tiny. In fact it is so small that it is easily swallowed by the patient.

Its inventors say that it then painlessly winds its way through the digestive tract and uses wireless technology to transmit full color pictures to a belt pack receiver worn by the patient. That unit also decodes the signal and records the information as the patient goes about his or her daily routine.

A U.S. spokesman for Given Imaging says that doctors who wish to use the video imaging pill will have to buy a specialized $20,000 computer workstation. Each camera capsule costs about $450.

For the Amateur Radio Newsline, I’m Mert Garlick, N6AWE, in Los Angeles. Roy.

--

The entire system is reminiscent of the science fiction movie "Fantastic Voyage." In that film a submarine and its crew of medical specialists are miniaturized and injected into the bloodstream of a critically injured man to perform an operation to save his life while receiving instructions by two way radio. (Science Today)

No I disagree. But then I am no expert. I know I had a terrible time tuning a 160 mtr dipole on 80 but I have no problem tuning 102 feet on 80.

Help me understand this because I sure don't and I know you do. Isn't it more accurate to say, "The moral is don't worry about using the antenna on even harmonics IF you can be sure your feed line is a multiple of 1/4 wavelength."

If the feedline is not a multiple of 1/4 (and it won't be on all bands) then you will be facing some rather large mismatches. If the feed is 1/4 wavelength, when you switch bands to the next even harmoic, the feedline will be 1/2 wavelength and your transmitter will see the nasty result: the exact impedance at the antenna.

Further, on the band where you are resonant, wouldn't the tranforming effect of the 1/4 wavelength feedline will take your 72 ohm antenna and turn it into a monster?

Look at Tables 1 and 2 of Chapter 25 (Coupling the Transmitter to the Line) of the 18th edition of the ARRL Antenna Handbook. It compares a 100 foot flat top to a 66 foot (40 mtr) inverted V. The flat top looks a lot tamer at the end of 100 feet of ladder line. The 40 mtr antenna has big impedances and large +/- J swings whereas the 100 footer looks a lot easier to match -- much lower impedances and +/- J.

Am I missing something?

Source record: 151016

I hear you on that. But if the other guy is 599 then I am only 5 7.5 9 so it still works. Interesting that the loss in 100 feet of ladder line feeding the 100 foot flatop antenna on all other bands is less than 1 db.

Are there other losses I should be concerned about?

> one that costs more has less gain, so they must be doing something else
for
> $1240.

The commercial Celwave antennas I've seen appear to be made of much thicker fiberglass and aluminum parts than the Diamond ham models. Hence, they are more durable and should withstand the environmental elements much better (proper installation of course) . Then of course, they are marketed to governmental and the business sector so the price is automatically escalated a few thousand percent and that is why they cost in excess of $1000.

>
> I'm worried about falling ice and high winds. I'd have no problem with a
> Diamond at my house, where the environment is much better.

The Diamond 500 I have seems to be very flexible and I would think would shed ice pretty easy. Diamond claims a 90mph wind cabability for the model 500 and a higher wind velocity for the shorter models.

Also, getting up
> 300 feet to replace a busted antenna is not something I will be able to do
> nor afford too often, hence the harsh environment requirement.

I would rather replace a ~five pound Diamond model 500 antenna that I can manage with one hand while tightening the mounting brackets that a ~30lb(?) Celwave. Eather way, I know what you mean, you don't want to climb that 300 ft tower. Man, are you lucky to have permission to install a ham antenna on such a tall tower. Now that little Diamond VHF x50 for $100 (or whatever equivalent UHF model) would surely survive on the tower.

>
> At this point, I've committed to going just UHF on the tower, so this may
> change the requirements a bit. I don't think any commercial antenna will
do

I'd stop agonizing, and just do the logical thing: find a reasonably well-built
ham vertical that covers 2 or 3 bands, put it up, and use it. If the weather
kills it, fine, go with a better-built commercial job for one band.

Depends on how heavy the vertical is. I've put two wood (1x2) pieces into a hole in the back yard, drilled an horizontal hole through them and the mast. I ran a 3/8 bolt through the holes to make a hinge. By mainpulating the mast, I have a foldover 10 foot mast for an R-7000. The antenna is very bulky and weighs about 28 pounds.

This is probably too much weight for the assembly, but it is still up after two years! If you have a lighter weight vertical in mind, it should work.

Good luck,

Bill, W4WNT

While I have the greatest respect for the folks who created the computer antenna analysis programs, I believe in trying lots of different antennas. I've built and used tri band verticals with elevated radials and used one coax to feed 2x40m and 1x80m antennas. I also have a 20m/30m dipole fed with one coax at 25 feet elevation. Worked Heard Is. with that one on 30m!! Keep the different dipoles at 90 degrees to one another.

Good luck and keep building.

This might be a dumb question, but so what.

How do you vary the length of the feed line?

Find ON4UN's excellent book on Low Band DXing. John spends quite a bit of time discussing elevated radials, which sound like what you can use here.

Good Luck,

Bill, W4WNT

Source record: 150924

I have a 5-band "trapped" dipole (W9INN MPD-5-78') as an inverted vee
at 54 ft and at 90 degrees to it a homebrew 17m inverted vee. 6
resonant antenna elements (bands) on one rg8x feedline.

That combo also, interestingly enough, is a 3:1 vswr on 12m (and
tunes up fine) so actually this is a 7 band arrangement on one
feedline. 300 DXCC countries in 6 years and counting.....

==========
Hello Ray,

I agree entirely with CAM. Cecil is not so talkative as he usually is. A simple end-fed inverted-L is the best all-round, all-band HF antenna there is, even when there's much more real-estate available than you have.

1. Use 18 to 14 gauge enamelled copper wire. Unless you live in a hurricane area it will last for years.

2. Make the vertical section as high above real ground as you can.

3. Make overall length as long as you can up to a maximum of 0.3 wavelengths at the lowest frequency you would like to use it at. This is roughly 160 feet on the160 meter band but is very non-critical. But you can expect satisfying reports even with overall lengths as short as 0.2 wavelengths, about 80 feet total on 160m.

4. A small advantage of the shorter overall lengths is a little better performance on the 15 and 10 meter bands. But predictions are purely statistical. At your QTH you may find things the other way about.

5. To increase overall length of an inverted-L turn it into an inverted U. Or if you have another tree available, go sideways few a few feet at the end to increase length. But again, it's very non-critical what you do.

6. The grounding arrangements for an inverted-L on 160m are an important consideration. But make your mind a blank about Marzipan-the-Magician's magic number of 120 buried radials using miles of wire. You can easily become bored with the number 120 in monthly magazines, annual handbooks, compendiums and in contributions to this newsgroup. At higher freqencies, 14MHz and above, ground electrodes, plates, rods, matter much less.

7. It is more convenient, faster and more reliable to test performance of this type of antenna on receive rather than on transmit. Make tests at the lowest frequencies you intend to use with signals from reliable strong broadcasters.

8, Let the first ground connection be to your domestic Hot/Cold/Domestic heating system pipes and 60Hz power supply ground.. They should all be bonded together, anyway, for domestic safety reasons. Do some test

9. There will be some improvement in radiating efficiency if some shallow buried wires (up to 12 inches deep but 3 inches is fine) are lumped together with the indoors domestic stuff. These 'radial' buried wires can be strewn at random under the antenna. If you must then follow the garden path. There's no point in having them longer than the height of the antenna. In good, fertile, moist garden soil there's not much point in making ground radials, buried at 10 inches, much longer than 1/12th free-space wavelngths, 40 or 50 feet.

10. If you have any wire left on the reel use it to increase the number of radial wires rather than their length.

11. If you didn't notice any improvement in performance by increasing the number of radials from four to eight, then stop. If you should get to 16 stop again. Nobody ever gets above 32.

Just recently I worked transatlantic (into Georgia) from the UK on 1.845 MHz on SSB using 70 watts into an inverted-L antenna, overall length about 150 feet. Ground electrodes = domestic plumbing + six radial wires, the longest of which is 50 feet at a depth of 10 inches. The other radials are much shorter. My signal strength was reported as S8 and obviously sufficiently above his local noise level. I have very good soil in which to lay my few radials. Soil conductivity is around 15 milli-Siemens (resistivity = 70 ohm-metres) at VLF. But at my old QTH I have worked stateside with a similar antenna and a ground conductivity of only 3 milli-siemens (sandy soil, 300 ohm-metres) using only 4 long radials (plus the domestic plumbing of course. Always include that.

I would bow to your visual experience. Thanks for the confirmation.

I would not have given this any thought if I had unlimited access to replace any broken antenna, but I think that in order to make ham radio not look too foolish, it would be better to go with something as good as the commercial guys (which means $1k) rather than the less expensive, and possibly more likely to break, Diamond. This has to be one of those jobs that goes up and people forget about, hence all the worrying.

I'm not the one installing the antenna: the commercial riggers will handle that, so weight is not my problem. I just have to provide the antenna and about 500 feet of coax real soon. Might as well take a big gulp and order something. Has anyone priced GOOD (as in Andrews) 7/8 hardline recently? Talk about OUCH ! I guess this is considered lucky?!?!

But thanks all for the comments anyway. I'll find out the makes and models of the existing stuff on the tower, as well as coax size, next week.

>Robert " A F 2 M"

Robert, if it is a single band vertical you can actually ground it as a solid mast to ground and shunt feed it. Quarter wave antennas for 40 and 80 and so on work just fine shunt fed using TV twin lead standoff insulators and plain old antenna wire fed up through the brown plastic insulators to the upstairs tap point.

You use either a decent transmitting variable for the capacitor, or you can use a cut to length chunk of RG-8 as a capacitor and it works forever with no problems.

Solves a lot of the lightning mitigation problems too! Tap point is about 31 feet up or so on 80 meters and about 15 or so on 40 meters fed this way.

Thread:

For low reactance high power rf termination resistors, lossy open wire transmission lines work nicely, they can be shorted or open on the ends, depending upon the situation, they can handle high power and are easy to match.

Make em out of steel wire, not copper, cut em to length "in situ" while monitoring performance...

> accurate to say, "The moral is don't worry about using the antenna on even
> harmonics IF you can be sure your feed line is a multiple of 1/4 wavelength."

This is a confusing subject. It is the SWR that you have to worry about, not
the length of the dipole. Whatever the SWR is when it is not 1:1, will transform
the impedance up and down the feedline. All the following impedances will result
in an SWR of 9:1 on 450 ohm ladder-line: 50+j0, 4050+j0, 2000+j2000, 2000-j2000
In fact, there are an infinite number of points on an SWR=9:1 circle and any
of those points could conceivably be the antenna feedpoint impedance and/or
the impedance seen by the transmitter. The point is that all possible points
on an SWR circle can look identical at the transmitter. Therefore, all possible
antenna feedpoint impedances that cause an SWR of 9:1 result in the same
conditions at the transmitter depending on the length of the 450 ohm feedline.

Moral: An antenna with a feedpoint impedance of 4050 ohms is just as good
and just as bad as an antenna with a feedpoint impedance of 50 ohms when
one is using 450 ohm ladder-line to feed it. You can get in exactly as
much trouble with a 50 ohm antenna as you can with a 4050 ohm antenna
because the impedance possibilities at the transmitter are identical
in both cases.

If you feed a 50 ohm antenna with an odd number of 1/4 wavelengths of
450 ohm ladder-line, you will encounter 4050 ohms at the transmitter
which is *exactly* the problem as when you feed a 4050 ohm antenna
with a multiple of 1/2 wavelengths. Avoiding a one wavelength dipole
does NOT avoid the problem. Sticking with non-resonant lengths of
dipole does NOT avoid the problem. Using a 1/2WL dipole does NOT
avoid the problem.

Cecil

Thank you for the explanation. I think we just took a trip around the Smith Chart and I understand the issue better now. For every antenna, and every SWR, there is a corresponding length of feed line that will result in a 1:1 SWR at the transmitter. That is the basis for your No Tuner Antenna. So far so good. I may not understand how to use the Smith Chart but I follow the concept.

But the next question is "What is the common denominator?" If one is going to use a fixed length of feedline, what lengths of antenna and feed have the best chance of success on all bands? Instinct tells me to avoid 1/2 wave antennas and 1/4 wave feedlines because at some point (even harmonics) they are going to present very difficult matches. In frustration, I throw up my hands and say, "pick something that is random on all bands." Is there a better answer?

Here are some results using EZNEC/4 with the NEC-4 calculating engine.

There are two factors which affect the field strength from a vertical. One is the loss incurred by the returning ground currents. This is I^2*R loss, and is minimized by adding and/or lengthening the radials. (I'll show that sometimes, lengthening the radials hurts instead of helps.) The fraction of power that's radiated by the antenna rather than being lost in the ground is the antenna's efficiency. Improving the efficiency makes the signal stronger but doesn't affect the pattern shape. An arbitrary number of radials can be put in to make the efficiency approach 100%.

The second factor affecting the field strength is the reflection from the ground. This reflection combines with the direct radiation to form the vertical pattern. Because of loss incurred when a vertically polarized signal strikes the ground, the result is severe attenuation of low angle signals when the reflection takes place from a poor conductor like typical ground. (I'm considering only the far field sky wave here, although the ground wave is also attenuated more or less rapidly depending on the ground characteristics.) The loss that occurs depends on frequency, angle of reflection, and ground characteristics. I'll call this "reflection loss" to distinguish it from the I^2*R loss from returning ground currents. While elevating radials or using a half wave radiator can reduce ground currents and thereby improve efficiency, they don't affect reflection loss except in that the angle of reflection from the ground might be different because of different antenna height or current distribution. Laying out radials does have some effect on the reflection loss, but only for reflections that take place within the radial field. Unless radials are extremely long, this generally means that only higher angles are affected.

For most of the following tests, I report a the total of the two losses. EZNEC 3.0 incorporates a feature of NEC called "average gain". This is a calculation of the total power at all azimuths and elevations at a great distance, compared to the power being fed into the antenna from the source or sources, and is what I based the results on. I did separately compute the efficiency in a couple of cases -- I'll point those out.

For a single radial buried 0.1 meter, ground dielectric constant = 1, frequency 3.75 MHz, vertical and radial each 20 meters long, the maximum loss occurs when the ground conductivity is 0.65 mS/m. This is less conductivity than the poorest soil commonly listed in most tables. If the ground has a dielectric constant of 10, which is more common, the maximum loss occurs with a conductivity of 1.3 mS/m. This is about equivalent to dry, sandy ground or urban industrial areas.

The ground conductivity at which loss is maximum depends on frequency as well as dielectric constant. The antenna and radial lengths and radial depth were scaled for 14 MHz, so they remained the same in terms of wavelength. With a ground dielectric constant of 1, the conductivity giving the most loss was 2.5 mS/m, about the same as dry, sandy ground. With a dielectric constant of 10, the conductivity giving the most loss was 4.4 mS/m, about the same as average ground, heavy clay, or pastoral areas.

To independently check the effect on efficiency without regard to reflection loss, I compared the field strength from an antenna with no I^2*R ground loss (by modeling a plain vertical over EZNEC's "MININEC-type" ground model) to the field strength from the test antenna. For this I had to add a second radial because otherwise the pattern shape changed with ground conductivity. With two radials and broadside measurement, the pattern stayed the same for the test vertical and the reference vertical, enabling a valid comparison. Back to 3.75 MHz, with dielectric constant of 1, the maximum loss (minimum efficiency) occurred with a ground conductivity of 0.55 mS/m. With dielectric constant of 10, maximum loss occurred with conductivity of 1.0 mS/m. This raised the question of whether the conductivity for maximum overall loss was the same for two radials as for one. The answer is that they're nearly the same but not quite. For two radials, the overall loss with dielectric constant of 1 was maximum for a conductivity of 0.45 mS/m (vs 0.65 for one radial), and 1.0 mS/m for dielectric constant of 10 (vs 1.3 for one radial). So over the range of testing, the overall loss was minimum at roughly the same conductivity for one radial as two, and at roughly the same conductivity as the conductivity for minimum efficiency. The minimum efficiency for the two radial case, incidentally, was about 25% -- field strength is 6.0 dB below perfect when the dielectric constant is 1, and 5.1 dB when the dielectric constant is 10.

Now, here's another effect I mentioned in an earlier posting. If the ground is really lossy, the radials effectively "disappear" as you get farther from the antenna, since the current on them drops rapidly as you go outward. When the ground isn't so lossy, though, there's substantial current all along the radial. And it turns out that the efficiency really goes to pot if the radials are allowed to become near an electrical half wavelength long. It's important to realize that this is the case for elevated radials also. At 3.75 MHz with a ground conductivity of 0.1 mS/m and dielectric constant of 10, the velocity factor of a plane wave in the soil is 0.32. With the same conductivity but dielectric constant of 40, the velocity factor drops to 0.16. At 3.75 MHz where the wavelength is just about 80 meters, a free space quarter wavelength is 20 meters. Deep in soil where the velocity factor is 0.16, a quarter wavelength is only 3.2 meters, and a half wavelength is 6.4 meters. Near the surface, a quarter or half wavelength will be a bit longer because some of the field is in the air. However, a radial doesn't have to be buried very deeply to have an electrical length pretty close to these figures.

So I modeled a 20 meter high, two-radial vertical with radials 8 meters long at 3.75 MHz with ground conductivity of 0.1 mS/m. This is lower than most soils, but I chose it to clearly illustrate the effect. This effect can easily be shown for elevated verticals using NEC-2 based programs (but not MININEC based programs). I watched the overall loss as I increased the dielectric constant from 1. At 1 it was 14.6 dB, then dropped monotonically until the dielectric constant reached about 20, where the overall loss was 5.7 dB. Then it rose sharply, to a maximum of 11.9 dB at a dielectric constant of 34. At that point, the velocity factor deep in the soil is 0.17, and somewhat greater when close to the surface. The velocity factor for the radials buried 0.1 meter is apparently about 0.2, making them a half wavelength long. By *shortening* the radials from 8 to 6 meters, the loss was reduced from 11.9 dB to 5.0 dB, a 6.9 dB improvement. This is almost entirely an improvement in efficiency, since the overall reflection loss is affected very little by a change in the length of two radials.

The same effect can be shown by leaving the dielectric constant fixed and varying the conductivity, but the results get muddled by the fact that the radials increasingly "disappear" and the ground reflection improves as the ground becomes more conductive.

In summary, the value of soil conductivity that produces the maximum loss depends on the soil dielectric constant, frequency, number of radials, and radial length. I believe it also varies some with antenna height, although I didn't test that hypothesis. Shortening radials can sometimes improve the efficiency, particularly if the radials are elevated or the soil is a poor conductor.

Ground modeling is one of the things that common programs probably do worst. The main shortcoming is the assumption that the ground is homogeneous to an infinite depth, while real ground can vary a great deal with depth, in both soil composition and moisture content. So it's impossible to say how closely the results from a program will agree with actual measurements in a given location when ground characteristics are an important player. Nevertheless, we can gain valuable insight about what's happening by observing the model's behavior in the sanitized world of the modeling program.

Note: Each time I make a posting mentioning NEC-4 or EZNEC/4 I get a number of queries about where to obtain it. NEC-4 is copyrighted by the University of California. It's distributed by Lawrence Livermore National Laboratory (LLNL), and is restricted to use in the U.S. by U.S. citizens. (I don't make the rules, but I sho' 'nuff abide by them.) The cost for a license is $850, although there's a discount for universities. Anyone wishing to purchase EZNEC/4 (which is $600) must first purchase an NEC-4 license from LLNL, which I verify by contacting LLNL. I'll be glad to pass along the name of the person to contact at LLNL for information or to purchase a license, to anyone seriously interested.

>. . .

No, that isn't so. You can verify this on the Smith chart. If you normalize the chart to the transmission line impedance, then 50 + j0 ohms, generally what you're trying to match to, is a specific point on the real axis. For example, if you're using 450 ohm line and normalize the chart to 450 ohms, then the point 0.111 + j0 on the chart represents 50 ohms. With the chart normalized to the transmission line impedance, you'll see that changing the line length takes you in a circle around the center of the chart. Wherever you start from, all you can do is traverse a circle. So you see that from any given point on the chart, you can hit the real axis at only two points if all you can do is change the line length. You might get lucky and have one of these be close to 0.111, or you might not. You can't guarantee it.

To get a perfect match to an arbitrary impedance you always have to be able to adjust TWO things. Think of it as adjusting the R and the X or the magnitude and angle, although the adjustments really never operate that independently.

I have a very similar dish (Winegard 10ft) and two or three of the mesh panels have slipped out, so I will have the same problem when it goes up next summer. My idea (untested as yet) was to make one or two "grippers" with several protruding nails to engage with the mesh, to help with sliding them back into the slots.

Thanks to Bill's advice, I will also spend a lot of time cleaning out the slots, flattening the edges of the panels, and greasing everything thoroughly!

Multi-band dipoles work!

I have been using multiband dipoles made from multiconductor cables for years. They work very well.

I am a USCG captain and offshore sailing instructor. I go offshore all the time, sailing 40-60 footers all over the Western Atlantic, Caribbean and Caribbean. I take an Icom SSB, manual tuner and a heavy duty, made up, multiband antenna with feed line, with me on all my trips. The set up is a snap. I have developed the design over several years of trials. I hoist it either vertically or as an inverted "V" on a spare halyard. I usually use it vertically to minimize the interferenace with the sails. My most recent antenna, now in use two years, is made of a four conductor, round, Romex type cable. The conductors are 18g, (three insulated, one bare). It therefore enables four independent dipoles. I use a strong nylon center tie-point / insulator. It is fed with about 45 ft of RG-58U. The dipoles are cut by trial and error to present the lowest SWR at the center of the various bands. In my experience the lowest SWR is still higher on most bands than it would be with a single free space dipole. Max SWR is about 5:1. But the manual tuner reduces it to 1:1 on all bands. Signal reports are very good, comparable to any other maritime mobile or base station running a conventional backstay, vertical or single wire antenna. The system is essentially groundless but I am sure the operation over saltwater improves the signal propagation on earth bounces.

NEC does not enable modeling this type of antenna. I would also like to know how to better model and design this antenna using software so as to avoid the trial and error in the cutting process but what I have works! I am wondering if software which is designed for modeling transmission lines would be more applicable to designing this type of antenna than software designed for modeling an antenna.

Hi Reg,

I am also planning on putting up an inverted L. If it does well enough on 80m, 40m, and 17m I will be taking down my inverted Vs for these bands. This is for aesthetic reasons only.

I see the ARRL handbook says to use a variable capacitor of around 500-800 mfd between the earth ground and shield of the coax. The handbooks version also has an overall wire length of 165 to 175 ft. You didn't mention anything about using a variable capacitor. Is it necessary? Or can I just hook the shield directly to the ground rod I have at the base of the pole I will be hanging the L on. It's a 40 ft utility pole with a 4 element tribander on top.

Tnx,
Bill

I have a two band dipole 20/12 meters. I put it up and get a 2:1 on the frequencies of interest. I tried to model that on EZNEC. I (just now) finally have a model that comes pretty close to what is in the air. The 20 meter is 180 degrees. The 12 meter is 120 degrees. When I changed the elevation of the 12 meter from 180 degrees to 120 degrees, the program changed the length of that dipole. I don t know what length is in the air. Getting both of them to a respectable(?) SWR was tricky and using my Autek it was just fold over and try(no more cutting). I wonder if the program gives a fairly close figure for what the length of 12 meter dipole should be. Will have to lower it today and find out. (I am using #16 insulated wire and I understand insulation can lower the electrical length of the wire by about 2 %.)

I believe your counter mentioned 50,000-plus visitors. 4% of that is 2,000
Netscape visitors -- not a small number.
>
> I think you might like Netscape 6.2..

I use an older version of Netscape (it's an older computer with limited memory)
and am not interested in upgrading Netscape on this machine.

After visiting your site last night, I had trouble shutting down my pc; had to
reboot before it would shut down.

>it is a nice looking internet
>suite......thanks for letting me know about this performance issue.....

It would seem, in the future, when you advertise your site in the newsgroups,
you might put in a disclaimer warning users of older versions of Netscape that
your site is incompatible.

Thank you,

Bob

Vertical stacking is more effective for DX because of the lower angle of radiation, fewer skips and less multipath. It also has much less inertia, which varies as r squared, so it's easier to turn. The beam pattern is also less sharp, so it doesn't have to be pointed directly.

Hello Bob,
Thanks for dropping by my site and also for sharing your comments with me. FYI I have added a line of text to the homepage that states the " site is optimized for use with IE 6 " .

The internet and all of cyberspace is an ongoing and evolving scenario and for web designers 100% browser compatibility is at best a " moving target ".I strive for cross-browser compatibility and test my site against IE 5, IE 6, Opera 6, and Netscape 6 since these represent the current offerings from each respective camp.

Each day the older browsers (such as the v 4 series) become less and less compatible because they were written before much of what has now become html standard code was ever produced. Just a fact-of-life on the world wide web....thanks again....

Nope, what you say is true only for antennas that have an SWR = 9:1 on the 450 ohm ladder-line. Real world antennas can have virtually any SWR on the 450 ohm ladder-line. If the 450 ohm SWR is 4.5:1, the lowest impedance point along the feedline will be 450/4.5=100 ohms giving a 50 ohm SWR of 2:1. If the 450 ohm SWR is 18:1, the lowest impedance point along the feedline will be 450/18=25 ohms giving a 50 ohm SWR of 2:1. My method of matching relies upon the 450 ohm SWR being between 4.5:1 and 18:1 yielding a 50 ohm SWR less than (or equal to) 2:1. Fortunately, for dipoles that are 1/2WL at the lowest frequency of operation, the 450 ohm SWR does indeed usually lie between 4.5:1 and 18:1 which are two SWR circles on the Smith Chart. These two SWR circles form a doughnut on the Smith Chart. Any feedpoint impedance within that doughnut is acceptable to me. I will upload that particular chart to my web page. For frequencies above the resonant frequency of a 1/2WL dipole, the feedpoint impedances tend to be within that doughnut. For frequencies below the resonant frequency of a 1/2WL dipole, the feedpoint impedances tend to be outside of that doughnut. Moral: If possible, avoid short dipoles.

> and 1/4 wave feedlines because at some point (even harmonics) they are going to
> present very difficult matches. In frustration, I throw up my hands and say,
> "pick something that is random on all bands." Is there a better answer?

Picking something at random will guarantee failure on some bands unless one is extremely lucky. And let me say this one more time:

For dipoles that are 1/2WL at the lowest frequency of operation, there are NO DIFFICULT MATCHES using 450 ohm ladder-line or open-wire line. There are difficult matches for short dipoles but not for long dipoles. With extremely short dipoles, there may be NO length of ladder-line that will make the tuner/transmitter happy.

The better answer is to install a way of varying the length of the ladder-line. On my web page, I describe how to do it with relays or knife switches. There may be a better way than mine but I haven't thought of it yet.

The other thing to note is that the feedline length doesn't need to be exact if you are using a tuner. For instance, with a 130ft dipole, a

450 ohm feedline length of 94 feet will get you close on 40m, 15m, and 12m. A length of 102 feet will get you close on 30m, 17m, and 10m. And a length of 110 feet is good for 80m and 20m. If one goes this route, only two 4PDT relays or switches are needed. This approach will usually work with internal antenna tuners. And, as a bonus, feeding a transmission line at a current maximum point (impedance minimum point) tends to minimize common-mode currents based on my measurements.

Most everything I've said can be observed using the free demo version of EZNEC available from www.eznec.com.

A LOT more money than copper wire, but the GAP antennas work very well. The 160 model also handles 80, 40, & 20. It uses three decoupling "radials" of some 56 feet, as I recall, and can be mounted on the ground or elevated (three guys). Remember, most man-made QRN is vertically polarized. Slopers can also work very well, but may initially require extensive adjustments of length and slope angle to work really well. My first DX on a quarter-wave 160 sloper was W6 to Lu, on SSB, well before sunset! (A few years ago.) Of course, it worked so well because I put it up at night in the rain.

Source record: 150968

Hello Bill,

The inverted-L I have in mind does not have any coax. The antenna wire comes right into the shack to the tuner. The domestic plumbing system can then be included in the grounding system. The only coax is a short length between tuner and transceiver. But I appreciate there are circumstances when the inverted-L feedpoint may be some distance from the house and there is then some need for tuning or matching at the junction of antenna and coax. Keep the coax as short as possible or they may be tuner problems at the higher frequencies.

When there's a longish length of coax between antenna and shack I can see no reason for connecting a variable capacitor between coax braid and ground. In any case the coax braid is always directly grounded at the transmitter end which tends to short-circuit the capacitor.

But there is a VERY good reason on 160 meters for connecting a 500pF or more, variable capacitor between the antenna wire and coax inner conductor, with the coax braid being directly grounded via some radials at the antenna end.

When the inverted-L is 30 or 40 feet longer than 1/4-wavelength on 160 meters the antenna input impedance is an inductive reactance of several hundred ohms in series with a resistance between 50 and 100 ohms. A 500pF variable will tune out the inductive reactance to leave a nice pure resistance with a value in the right ball-park.

In fact, if you are interested only in 160 meters you won't need a tuner, the 500+ pF capacitor will be sufficient. If you like, prune overall antenna length to make the input resistance EXACTLY 50 ohms. Increase the length to increase feedpoint resistance.

By far the weakest link in your arrangement is the solitary ground rod. Even 3 or 4 spaced ground rods will give poor performance unless the soil is very fertile and moist. So I suggest you do your best to lay down some radials. Even only two, 25-feet long, 10 or 12-gauge, shallow-buried radials will be noticeably better than one rod.

Download program ENDFEED in a few seconds from website below and run immediately. It covers the points mentioned above and a lot more besides. It will predict antenna length to give Rin = 50 ohms and the capacitor pF needed to tune out the inductive reactance. The usual SWR meter indications are all that's necessary to set it up.

Definitely an option I have considered... For purposes of providing a
decent counterpose for the antenna, however, there are very few decent
locations in which I can install the antenna... A treetop in the back
portion of my lot DOES present itself as a possibility...

Thanks for the vote for inverted-L, have a good friend who's using
one, can always get him to help me build mine..

SNIP!

Reg,
Thanks for the post. Printed out the details, will share them
with my own Elmeer (yes, even Extras have Elmers!). Two votes for the
inverted L. We live in the Northeast, soil here, I would assume is
relatively moist and should be fairly conductive. Perhaps the
requirement of an assymetrical grounding array won't be TOO much of an
impediment to working an omnidirectional pattern. Hell, maybe my
neighbors would actually LET me bury some ground radials under their
yards!

Any one have a good estimate for a yagi antenna noise temperature, in
degrees Kelvin, pointed at the horizon at a receiving frequency of 600mhz ?
My guess is between 100 to 300 degrees Kelvin, any better guesses ?

877. Re: conjugate matching

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-13 17:09:24 UTC
From: Robert Haviland <bobh@iag.net>
Message-ID: <8bj08.27893$zw3.2719699@newsread1.prod.itd.earthlink.net>
Source record: 150963

The main problem with conjugate matching is the mis-interpretation of the definition.

Consider a generator with characteristics Zg=Rg+jXg. To it is tied a load, described by Zl=Rl+jXl. The conjugate match theorem states that maximum AVAILABLE power is delivered when Xl=-Xg. Note the word "available", which means available to the resistance Rl.

There is a lot of confusion caused by neglecting the word "available". This leads to assuming that the condition is for maximum power transfer. This requires two independent settings:
-matched load resistance, Rl=Rg
-Conjugate reactance, Xl=-Xg

Actually in RF power generation we don't want maximum power transfer. The reason is that half the total power is burned up in the generator, and half is delivered to the load. In a good Class C amplifier, only 30 percent of the total power is burned in the generator, and 70 percent is delivered to the load. Look at the difference for a KW of output:
30-70 design- 428 watts in generator, 1000 watts in load, 1428 watts to pay for (=1000/0.7)
50-50 design- 1000 watts in generator, 1000 watts in load, 2000 watts to pay for, plus bigger and more expensive tube, power supply, etc.

The operation of "tuning up" an amplifier involves getting a conjugate match.
"Tune to the dip" of plate current by adjusting the "tune" control automatically creates a
conjugate match. It may not be the right one, so changing the "load" control is used to bring Rl to the right value, usually down, which also usually involves touch-up of the "tune" knob. The process is so easy and automatic that we don't need to think about it.

If you have a problem with this, draw a generator and load and calculate a few examples. Or see my article in the December 1997 issue of QEX, published by the ARRL.
Have fun

Or better still quit "advertising" in usenet, period. But I know better than that so...

I too use an older version of Netscape and I'm damned tired of cybergeek web page designers that assume everyone has the latest software, a 1 GHz processor with 1 Gbyte RAM, a 35" monitor, a dedicated T1 line and wants to look at their product via streaming video.

If these folks want me as a consumer, they are making a big mistake.

There are few nice things to say about the nation's telephone companies anymore but one of them is that they understand backward compatibility. You don't have to buy a new telephone every six months to keep making phone calls. In fact your old 1950 rotary dial handset should work just fine.

Telephone companies are run by business people who realize that they need to keep *all* of their customers, not just the ones with the latest whiz-band super-duper handset with a 1 GHz processor, 3-D video and your choice of "designer" color.

That 165-175 ft is for a longer L. Usually when this is done, it's to
raise the point of maximum current off the ground to lower ground
losses. It usually increases efficiency a bit, but it adds more
horizontal componant to the pattern. For regional work this is ok. For
hard core dx, you'd probably want to stick with a 1/4 wave. When you
use an extended L, you need the series cap to tune out the reactance.
A 1/4 wave L doesn't need this cap. Yes, on most the shield is
grounded at the base to the radials or whatever. Also, if you want a
real clean vertical pattern will a low amount of horizontal, add
another top wire and turn the antenna into a T. At this time, I have
both a 1/4 L about 45 ft tall, and I also have a T which is 42 ft tall
and a 1/4 wave top wire. Actually the way I have it set up, when
shorted together it has 4- 1/8 wave spokes as a hat. Max current on
that antenna is near the top of the vertical section. It seems to
usually outplay the L most of the time. I don't have many radials at
all yet. About 4 under the L, and 4 short ones under the T, with the
grounds connected to the water pipes also. Our pipes are all metal
where it counts. I want to add a bunch of short radials later as a
test. MK

TH-7DX, 7 element, broadband Tri-Band Beam for 10, 15, and 20 Meters. This amazing tri-bander, using a dual driven 7 - element system maintains a VSWR of less than 2:1 across all bands, including ALL of 10 Meters. No compromise on gain performance was needed to achieve this efficiency. A unique combination of trapped and monoband parasitic elements produces a front-to-back ratio of 27 dB. The antenna includes exclusive diecast aluminum, rugged boom-to-mast clamp, and heavy gauge element-to-boom brackets.
The current new cost is $819.
TH-7DX tri-band antenna has a wind load of 9.4 Square Feet, Boom length of 24', Turning radius of 20 Feet, Longest element 31 feet, weighs 75 pounds, and will take a mast from 1.5 to 2.5 in.
This model is still in the Hy-Gain line. I used this antenna to work 335 countries on phone & CW.

Reg,
Just as a bit of grounding information, I've found that using
the 'plumbing' can also cause problems, depending on where you
live. Since the ground becomes part of the radiating system, and
if you live in a multi-family dwelling, you've put your 'antenna'
in everyones home. Not exactly the thing to do to keep RFI down.
Same goes for using common fences around your/their property.
Does
this hold 'true' in every case? Of course not, but it is one of
'those' things to remember...
'Doc

Roy,

I have a couple of current baluns in service for my own equipment and a goodly number of the local ARES folks use the same type: # 823 from http://www.thewireman.com/baluns.html .

Source record: 150877

The transmission line models in EZNEC and NEC are only good for representing non-radiating transmission lines, not something like an antenna. The program will do a good job of modeling close spaced parallel conductors, whether used as a transmission line or antenna, with some cautions and limitations. The conductors must be spaced at least several wire diameters apart, and the segment junctions must be aligned to be directly across from each other. These are explained in the EZNEC manual in the topic found by looking up "Closely Spaced Wires" in the index. EZNEC isn't able to account for the dielectric between conductors in something like the original poster described. So although EZNEC or NEC-2 can model a multiple conductor dipole, the wire lengths won't be the same as for a real dipole made from multiple conductor insulated cable. I'd also expect the real one to be somewhat more narrow banded than an air-dielectric EZNEC model with greater wire spacing.

Programs intended for modeling transmission lines invariably assume, as EZNEC does with its transmission line models, that the line doesn't radiate. That makes these programs unsuitable for modeling any kind of antenna.

I assume you want a vertical for dx reasons? If you used a hat, it's not going to do much good down at the coil. You would want the hat spokes at the top of the 65 ft wire, and sloping downwards or whatever. But then you have the problem of unhooking them from the system for 80m. Seems to me it would be easier and more effective to just put up a normal 80m dipole some way, even if the elements are in a horizontal V. Use a feedline that is the appx length to make a 1/4 wave on 160m counting the antenna legs. IE: If you used an 80m dipole which is 60 ft a leg, and used a 60-70 ft long coax, and then shorted the center pin to shield at the shack, you could feed it like a T vertical on 160m. You can use the tuner to get a good match if needed. You would have normal dipole performance for 80m, which is really better than most verticals unless you work only dx, and it will work fairly well on 160m as a T. Being no coils are used, it's fairly efficient. The only downside is you are feeding the 160m direct from the shack. But I've found it really doesn't hurt you too much on that band. I've got an inv L fed normally from a ground point in the backyard, and I use my 80 turnstile as a crossed T vertical fed direct from the shack. It is the best usually. But that could change if I added a bunch of radials to the L. If I added radials for the T, I'd want to add them from the shack out I guess. I'm lucky here in that the ground cdx are pretty good. I could feed it from ground also if I really wanted to. Actually , I made a relay setup a few months ago to be able to switch at the base of the mast, but the dang relay contacts caused me extra AM-BC qrm, and I had to junk that idea. The downside was worse than the plus...:/ So I went back to feeding direct from the tuner. I'm still having a problem of very strong AM-BC energy near my mast and around the house. This seems to have slowly cropped up over the past few months. I've been thinking external rectification, but I haven't been able to find anything so far. I'm now starting to think it may be related to all the rain we have had this year, which was near record breaking, and the improved ground cdx and increased AM signal strength which I bet I have. Dunno...About to drive me nuts. It doesn't bother my 830 much, but it does my 706. And the 706 was pretty clean a year ago so it's gotten a lot worse in the past year. Either or the radio is broke. I thought maybe the 706 had a problem with the BPF's, but I can't find any problems so far. Seems to be an increased

local RF level and the radio just can't handle it. I know my mast, all the above ground electrical conduit, and even my water heater is HOT with AM-BC RF. Really weird...MK

This really must be a reactionary group. Two people have said they use an older version of Netscape, and I'm a third. I read so many tales about ugly problems in Netscape 6, I've never upgraded from the version 4 I've been using for years. I almost never encounter a site that doesn't function properly with version 4. Besides a general dislike for Microsoft's attitude and way of doing business, I like Netscape because a lot of hackers share Charles' attitude and don't bother spending much time figuring out how to exploit Netscape's vulnerabilities.

I've been out of ham radio for about 20 years.

Does anyone still make "Grid Dip Meters" (or are they called something else, now that there are no more "grids?") A search on google just turned up a lot of old surplus equipment and ancient photos.

I would have expected there to be nice digital ones these days.

Charles-
Your arrogance continues to astound me- for your information-
I have the older version (4.7) and at least two of the 6.x versions on my machine, and have done A/B tests. in all cases, the older version is better, in my opinion. The newer version takes MUCH longer to load, and is no more problem free. Everything it does takes longer on the same machine.

It is interesting that Netscape did NOT abandon the 4.x versions when 6.x was found to have so many problems, even after the "fix" publication.

I no longer visit your site, and consider myself wise. My earlier visits were irritating, because of the music. The later visits were no better.

MFJ still makes one, a model 201 dip meter for 1.5 to 250 mhz. Try the MFJ web site...

Otherwise, I have one I built back in the 80s, a Heathkit solid state "dip meter." You can find them occasionally on ebay. There's generally a few vacuum tube models for auction, too -- they're getting to be quite teh collector items, especially the Millen models.

Doc,

You are quite correct to advise readers of the possibility of RFI sneaking in to neighboring flats via common water, gas and electricity services. It gets around as easy as from one room to another in an ordinary house. Sometimes precautions may be needed and this is often dealt with more conveniently and efficiently at the equipments being interfered with.

It is much less likely to sneak into a separate house next door because of high attenuation when the services run underground. As is well known the loss in buried radials is high.

But in any case, the transmitter ground terminal is always connected to the electric power ground which in turn is bonded to domestic water pipes and any other services in metal conduits, for reasons of safety.

Most people run no more than 100 watts of RF. I wouldn't recommend using the domestic plumbing system as the sole ground for a 1 KW transmitter. But I would always connect an external RF radial system or RF earth-plate to the incoming water supply pipe near to where the pipe enters the premises.

RFI between separate houses and gardens in suburban districts, specially when the antenna is not sharply directive, is almost always caused by direct radiation from the antenna. The far smaller amount of power which might sometimes be radiated from a feedline is negligible in comparison and rarely a problem with neighbours.

Hi Jerry,

No Iï¿½m not a teacher. I'm an electrical engineer.

No you don't need to cut your dipole to an exact 1:1 VSWR. However, if you are planning on using the dipole for one band. Then its worth while to adjust the antenna for minimum vswr.

You don't need to place the transmatch at the antenna. As you stated, the antenna tuner will re-reflected the reflected power back to the antenna minus any losses. However, there are two important things to remember. You need to use low loss transmission line and it has to have a high break down voltage rating. This is especially important when using coax. Coax is not as forgiving as balance line. Coax with a high VSWR will have higher losses and with high power, there is a danger of exceeding the breakdown voltage rating of dielectric. So if you're planning on running 1500 watts and using coax. I would recommend keeping the VSWR to reasonable level and use RG-213 or better. The Rg-213 dielectric has breakdown voltage of 5000 volts and by they way becareful of the pl-259s too they have breakdown voltage of only 300 volts. I like N connectors myself. The breakdown voltage is 1500 volts.

You mention that you want to use a single wire dipole for multiband. You are on the right track. Just cut your 40-meter dipole and feed it with ladder line. A good flexible tuner you should be able to match the antenna anywhere between 40 ï¿½ 10 meters. Just make sure you use a good current type balun with it. A lot of these antenna tuners have voltage baluns built into them. A current balun will keep the currents in each leg of the ladder line equal. If they are not equal the line will radiate. I've experience rfi trouble in the shack because of this. I have my balun mount outside and I use rg-8 to the antenna tuner.

As several of the others guys said in this thread, the dipole is going have multiple lobes. Some of lobes will be in the desired direction and some will not. You will also have nulls too. The whole thing is a trade off. You're trading one thing for something else.

I also used a butternut it worked great from 17 ï¿½ 80. 10 meters was ok but 12 meters sucked. I think the radiation pattern was shooting straight up. I had trouble with the 15-meter stub too. It was constantly losing up. I wish butternut would put a little more effort into mechanical construction of that antenna.

Reg,

Why do I get a feeling that you are setting this Yankee up?

Ok, I can't resist here's my answer to your question.

I don't think it matters. The principle is the same. You are matching
the generator to the load.

GW

You'll need to bond your "made electrodes" (ground rods)
to the house wiring grounding electrode system, per the
National Electrical Code. It was not clear if the first ground
("on the other side of the house") you mentioned is already
part of that system or not. You might want to take a look at
the PolyPhaser web site to read about lightning protection.

==========

GW, I'm really quite harmless. ;o)

You are right - it doesn't matter - because you are NOT matching the generator to the load.

All you are doing is setting the load to some particular value such as 50-ohms. That occurs when the SWR meter indicates 1:1 and you can feel happy.

You cannot match the load to the generator because you don't know what the generator internal resistance is. Not even the manufacturer will tell you. It is not included in the specification. Even the transmitter designer has no interest in what it might be.

50-ohms (or whatever) is the load resistance into which the PA will deliver rated output power without exceeding its internal voltage and current ratings or the maximum permitted internal dissipation. There may also be a specified level of signal distortion, and a specified level of harmonic generation.

Rated power output is NOT the maximum available power.

To draw the maximum available output power is likely to wreck the output transistors due to excessive collector current, volts, or power dissipation.

Reg.

Connect a 1", 2" or 3" diameter loop of wire from coax inner to outer on your Autek or 259B antenna analyser.

Slide the loop over one end of the coil or tuned circuit to be tested. Slowly vary analyser frequency looking for a sharp increase in impedance from zero ohms to several 100 ohms depending on coil Q.

Adjust closeness of coupling to the coil as necessary. Finish with loose coupling.

My AT-11MP does something similiar every now and then. I discovered a fix....

1.Turn the AT-11 off via the power switch on front panel.
2. Transmit a low power tuning signal with your rig (around 20-30 watts).
3. While the rig is transmitting, turn the AT-11 power switch back on (Auto/Semi switch in Auto position).
4. Mine then finds a match.

No idea why this is sometimes necessary...

You'll find no "dip meter" in any modern electronics lab. First, you design the circuit using one of the computer software design tools (Spice or the like), and finalize the design using a network analyzer. Much more accurate information. As for how do hams do it? I'm not sure that there are any tuned circuits in most modern ham rigs. All synthesized and digitally filtered. How else could you get a 100 watt transmitter and a receiver in a box the size of a IC-706 or TS-50?

>broadband them without resistive loading and dropping the efficiency
>and/or the Q too much. Looks like another compromise, or maybe too much
>of a tradeoff.

No compromise and no tradeoff.

Electric Radio #77 (September, 1995) has an in-depth article on the 600L and
the broadband couplers. They are a unique and ingenious design of four windings
that uses both mutual inductance and stray capacitance to do the job. The
amplifier delivers efficiencies of 60-65% on 160 thru 20 meters using a single
Class AB2 813. Efficiency on 15 and 10 is a little lower. Harmonic rejection is
greater than current FCC requirements. The couplers would work efficently into
an SWR of up to 2:1

Some QSTs of the 1960-61 era have ads for the CE products that briefly explain
the couplers, but not in much detail.

I won't try to describe how the couplers work here, because I simply can't do
the subject justice without a lot of diagrams. See US Patent #2.864,060

issued to Joe Batchelor in December, 1958 (application filed August 1955). Joe is the "father" of most of the CE designs.

Why did the idea not catch on beyond the 100V, 200V and 600L? Four reasons:

1) Because it was patented, other manufacturers would have had to pay royalties. The patent ran out in 1975, about when solid state finals began to be the focus of attention.

2) The design method is not described in the patent. It appears that the designs may have evolved by cut-and-try, and most homebrewers would not have the test equipment necessary to develop a set of couplers.

3) CE was bought out by Zenith in the very early 1960s, and the amateur line discontinued. The fabled 100R receiver never got beyond the prototype stage (the prototype still exists). Zenith simply abandoned the amateur radio products - kinda sad, considering where the Zenith name came from.

4) The pi-network had become the standard output circuit for amateur HF/MF transmitters. It was easier to design and bandswitch, and could be designed to have a wider matching range.

But the fact remains that more than 46 years ago Joe Batchelor had worked out all the problems of how to build a no-tune amateur radio transmitter using tubes, capable of hundreds of watts output.

Source record: 150907

Hi Spencer,

you might try a faraday shield.

tie the center conductor of the coax to your long wire and the shield to
nothing (be sure solder the connection and to seal the end of the coax with
silicone or some such against the weather). run the other end to the radio.
ground the inside end of the shield to your radio ground. you might want to
run it though a tuner for better matching (a little higher rx sig).
grounding
the outside of the coax causes any electrical noise from inside the house to
go directly to ground. should work well for receive.

another option is a t2fd (terminated tilted folded dipole) fed with coax.
see
http://www.radiohc.org/Distributions/Dxers/ttfd2.html
for directions on building this dipole antenna. i am currently building a
60
meter long version for transceive operation. i am using a transformer and
load
from b&w (commercial manufacturer). if you want to use this for receive
only
then the one on the web site will be sufficient.

if you decide to try one of these options drop me a line and let me know how
it
works for you.

As an ex-cable installer, I second your idea. I have done that
before...one particular installation was where the guy wanted outlets
OUTSIDE for temporary connections out on his deck, patio, etc. The
trick was doing it with no wires showing which meant poking thru the
back of his interior outlets.
You can get blank wall plates for this purpose and for outside you might
want to consider mounting a regular weatherproof receptacle box. That
will allow you to enter the box from the bottom (neater) and whatever
connection is inside will remain closed to the weather.
Drill from inside out so that plaster chipping can be covered by the box
:-)

hey phl
i have the same problem except that i dont mind a big gapping hole in the wall....grin
what you can do is if you can get into the attic is fish the cable thru the overhang into the attic then down the inside of the wallmy problem here is i have no access to the attic some idiot installed an attic fan in the only hole to the attic
good luck

Hello Raymond,
I had an inv-L up for 4 years before I had to move. It was 170 ft
overall length. In which abt 1000 Pf worth of cap across the leads
brought it to resonance. also closer to 50 Ohms. With a coil of
about 30 ft on a 2 in form, simply tap the shield and prune for best
SWR. This antenna had 12 radial under it @ 65 feet long. Quite
a goofy setup but it worked great. Best contact was VK. The height
of the antenna was only 60 feet. I can assume that any higher to near-
eqal height to top length would be even better. anyway gud luck and
73 from GA

Phil,
You can still do the 'through the window' thing with
the 'jalousy'(?) type windows, just takes a little more
effort. Some of those type windows have only a small
metal tab holding the glass in. Bend the tab out of the
way and replace the glass with plexiglas, or what ever.

You might have attic vents on the part of the attic roof facing downwards
towards the ground (I think it is called soffit).

If so, bring your cables under the roof line, up into the soffit, either
drill
holes in the wood soffitt or the attic vent. Then bring the cables down
inside from the attic ceiling into your interior room.

If your interior walls are wood, you can come down from the attic,
inside the wooden wall, and come out into the room through the
interior wall.

Good luck.

Hello all.
I am now living in a typical South Fla home, stucco exterior with those lovely awning-type crank-open windows, so replacing a pane with plexiglass isn't possible, as in previous dwellings. Before I drill a hole through the wall, as the cable guy did, does anyone have a neater way of passing the coax through the wall? I am thinking of putting some kind of plate on the outside, running RG8x through a hole, then another plate with a connector on the interior wall. Anyone have pics or description of a good entry through concrete block wall?
Thanks es 73

930. Re: Broadband Tank Circuit Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-14 05:16:45 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3C4269B8.40BF092F@att.net>
Source record: 150819

Another interesting development back in those days was the multi-band tuner
circuit that was manufactured by National and perhaps others. It was first
described in QST, if I recall correctly, as the final tank in a
bandswitching rig - sometime in the late 40's.

Actually, the notion of a series LC circuit in parallel with a C or L or a
parallel combination of both is pretty old as a means of obtaining multiple
resonances in a two-terminal network. The various C's can be ganged, etc.
to facilitate tuning. Makes a really neat tank circuit for up to 100 watts
or so. Again, if I recall correctly, link coupling from the various coils
was used to obtain output power, similar to the Z-match which came along
about the same time.

A friend of mine, K4KR, travels away from home and uses a Slinky antenna.
Check out his website http://www.k4kr.com/pics/portable.jpg.

You might also consider a loop from MFJ, if you have time to order one.

One last idea, most hotels have an outdoor area, such as an outdoor pool or
patio. You might consider working portable out on the patio area. Could put
up a small dipole, or vertical with a counterpoise.

[snip]

This is a little off-topic and it goes way back but perhaps shows why even "modern" labs should still have a GDO around.

About 30 years ago I was still a senior lab tech and was assisting a really fine rf engineer with a problem on a Phoenix missile i-f amplifier.

Phoenix is a monopulse radar bird and had (before we learned how to multiple the delta channel) a three-channel receiver. Each channel was gain and phase matched and had to maintain tracking with agc applied.

Each channel was on a separate board and each board was in a separate compartment in a dip-brazed chassis with a cover outfitted with knitted wire gaskets. The AGC line went from compartment to compartment via coaxial feed-thru capacitors. Power and blanking signals entered from a (fourth) separate compartment. The isolation between amps should have been very high but if fact there was crosstalk.

A couple of newly minted EEs had been working the problem without success. The old guy, (gads that's me now) Jim, was asked for advice. Jim studied the situation for awhile and then asked, "Wes, you gotta a grid dip meter around here?" Even thirty years ago, the new guys asked, "Huh? What's a grid dip meter?"

I said, "Sure", and produced a Measurements Corp GDO. (These are still these best there are and I have two of them at home).

Jim sticks the appropriate coil into the chassis and swished the frequency around and lo and behold, a nice dip quite close to the i-f. The combination of the capacitance of the feedthrus and the inductance of the connecting wires was resonant at the i-f. A change in the value of the capacitors fixed the problem.

When I retired, "my" lab had a megabuck worth of computer controlled equipment including a $200,000 H-P 8510C network analyzer, but I still had the GDO, despite the best efforts of the Metrology department (sorry Richard) to red tag it and call it "Inactive Equipment."

Wes N7WS

ps. Grid dip meters gotta have grids.

935. Tripod Mast Manufacturer - Ultimate

Newsgroup: rec.radio.amateur.antenna

Message-ID: <a1tllb$rqrju$1@ID-105647.news.dfncis.de>
Source record: 150915

I recently picked up a portable antenna mast system at a swap meet. The bottom section has a tripod base that folds out. On top there is a mast section with slides out of the base and locks in place with a thumbscrew locking mechanism. It comes with two more five foot sections of mast that sit on top, putting the whole thing about 20 feet in the air.

The entire assembly collapses down and is stored in it's own travel bag, about 5 feet long. On the outside of the bag, and on a sticker on the antenna is the word "Ultimate", which I presume is the company. The only other wording is some instructions for locking the antenna in place.

I've tried a few search engines, looking for the website of either the maker or someone who sells them, but so far no luck. Was wondering if anyone had one that could point me in the right direction.

Thanks,

Robert / N4IXT

936. Re: Which Came First?

Newsgroup: rec.radio.amateur.antenna

Source record: 150823
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Coming at it from both the Ham perspective and Broadcasting perspective:

KDKA was assigned 360 meters in 1920. As the number of stations grew, the band was expanded to 550-1500 kc. The hams, which were theoretically licensed to 200 meters (1500 kc) and theoretically only 200 meters, had some special licenses which went down to nearly 1350 kcs before the broadcast explosion, but at about the time broadcasting started needing a lot more space, i.e. 1923, the hams discovered short-wave, and ceased to need the longer frequencies. This was all somewhat suggestive, as the Department of Commerce had no real power to regulate frequencies until the Communications Act of 1927 placed such power in the hands of the Federal Radio Commission, the predecessor of the FCC. 1510-1600 was not added until the '30's, after the hams had vacated the frequencies, through an international shift in allocations by a treaty signed in 1927. 540 kc was not added until, I think, the 1947 Atlantic Conference. This would have been about the same time FM was shifted to 88-108 Mcs in the Americas.

So the hams had 1500 and up from 1912 until 1923, when a voluntary band plan gave them several bands, the first of which ran from 1500 to 2000 kcs until 1927, when it changed to 1715 to 2000 kcs. The AM band could not pass 1500 prior to 1927, as the 1912 law assigned 200 meters to Amateur Radio, and law outranks mere regulation. After the 1927 law was passed, the FRC had somewhat more latitude to assign frequencies, and the 200 meter restriction for hams was removed from the law at that time. Between the FRC's reorganization of the radio stations, now that it had the authority to do so, and the Depression, 550 to 1500 was sufficient for a good while. The original purpose of stations in the 1500's was to provide high fidelity sound, and were originally spaced 20 kcs apart. You must remember FM was only a laboratory experiment at the time this was going on.

I've studied this issue from both sides, having read both the League's 50th anniversary publication and 200 Meters and Down (reprint) and having a father who was in broadcasting for a good number of years. I also took broadcasting in college, hoping to follow in my father's footsteps.

In short, the answer was, serendipity. As the broadcasting band needed to expand, the technology became available to move hams into a different area of the spectrum, and to allow the broadcast stations to also broadcast closer together as well, as well as better receivers for those who listened to either group. Hams stumbled onto short-wave purely by accident. The engineers of that day said that anything above 1500 kcs

was totally useless, so no one had experimented much with it until about 1922.

I'd be interested in seeing a digital circuit to filter the output from a 100 watt transmitter or the input to an HF receiver. And also a synthesizer that's so clean it doesn't need any analog filtering.

By the way, my VX-5 is pretty new and about half the size of a pack of cigarettes. A glance at the schematic shows over 50 inductors, most of them in tuned circuits or filters. The answer to your question is that they do it by using really, really small components. But I admit you'd be hard pressed to measure them with a dip meter.

Add me to the list of those that will not upgrade until absolutely forced
to do so. All the recent browser versions seem to be riddled with bugs.

> BTW there is nothing inherent in the web page to affect your system
> from completing a proper shut down.

I have had mine lock up on occasion. But since it is a Windows NT machine,
I can use NT Security to kill Netscape. All other functions then operate
properly.

I am pretty sure it is the Java apps imbedded in many web pages that are
the problem, but cannot prove it.

Here is an implementation that brings 2 x LDF4-50 and 2 x RG-312 to a
patch panel which is based on a standard electical outlet.

The patch panel from the inside:

http://www.owenduffy.com.au/electronics/post08.jpg

The cable entry ducting on the outside:

http://www.owenduffy.com.au/electronics/post05.jpg

The duct was later painted to match the wall.

It is not unobtrusive, but there ain't an elegant way to get LDF4-50
into a wall mounted panel.

It would appear that you've fabricated much of the installation
yourself. Looks rather impressive!

I do have one suggestion. From a safety standpoint it's best if you bond
all your Grounding Electrodes (Ground Rods, etc.), including those
serving the electrical service, together with at least a #6ga copper
conductor.

Too bad you live in Australia. I would like to have you as a neighbor.

The biggest problem with the TV line is the extra loss when wet. Dry,
it's really not bad at all. But I agree, if I had my choice, I'd
rather have the 450 ladder line anyday. And at least #14 wire. Thats
another problem with the TV line. The wire is so thin. Some brands are
worse than others. A plus to the TV line is it's cheap, and you can
get it nearly anywhere. It's ok in a pinch, or for attic use etc. For
my short 15-20 ft indoor run to my attic antenna, changing to 450 line
from the 300 ohm would hardly be noticable. Outdoors, the 450 line is
much better. MK

I doubt it. The high bands should be ok, but the low band performance
will probably be fairly lame. I bet those autotuner inductors are kind
of lossy compared to a hi-Q loading coil. MK

There is an easy solution here.

You have a Hustler antenna on the car? You have the car. That gives you a good HF antenna system. If you want to set up in the hotel room, all you need to do is park the car near the room, and run some coax.

Didn't see one quite like mine. Here's a photo of it, if that helps.

http://www.mindspring.com/~robert.cain/ultimate.jpg

The black portion is what came with the mast system. The white thing is the middle insulator for a 20m dipole. The silver mast above that is a piece of aluminum antenna mast, attached to the top of it is a luggage mount SO239 and screwed on to that is a Hamstick (75 meters).

Thanks though, Fair Radio is a pretty cool site.

I would guess closer to 300 K. You would be picking up all kinds of
stuff from the ground. I wouldn't expect to be able to get 100 K when
pointing at the horizon. 100 K would be a good number if you tilted
it up and pointed it at the sky. Don't forget you'll need a good LNA,
too.

(I did my MSEE work at a radio telescope, by the way.)

In my mobile I am currently running a 102" whip antenna on 10m which works fine. However, I would like to be able to use it on 12m as well. What I would like to do is to homebrew a fixed L/C tuner (pre-tuned for the middle of the 12m band) that I can just switch in when I want to work 12m, and out when I want to work 10m with no knobs to fiddle with. It also needs to handle around 400 watts. I would like to wind my own inductor etc. for it so I would need the coil dimensions, value of C, a schematic to see how this would all go together would also be extremely helpful (this is my first project of this sort). Any assistance anyone can offer is greatly appreciated.

This is pretty much a nobrainer assuming you have an antenna analyzer
like the MFJ259. All you need is one series coil (no capacitor) between
the center wire of the coax and the whip feedpoint. Wind the coil and
test with the analyzer. If the resonant frequency is too low, take turns
off the coil and if the resonant frequency is too high, put turns on the
coil. About 4-5 turns on a two inch diameter coil form should do it.

But that's not a shortcoming of the program and does not detract from the value of the results. It is the understandable ignorance about the antenna's environment on the part of the user.

It causes just as much uncertainty in all other predictions, including radiation patterns.

Thanks very much for your efforts and time expended in obtaining the data.

Can we finally cease worshipping BL&E ?

Sorry about the Eric, I didn't pay attention to the model number. Went to the Bencher website and downloaded the manual for your model. If the matching section is functional, then as the Butternut tech suggested, it may be the 40M capacitor. Some multimeters have the capability of testing capacitors. Just because there is no short, the capacitor may be open, in which case you have a problem. If your VOM shows infinite resistance immediately without a resistance buildup over time, the capacitor is probably open. Amother option is to substitute a 40M capacitor from another Butternut to see if that helps.

Good luck.

On the basis that your antenna sees about half warm ground at say 300K,
and half cold sky, I 'd go for about 150K as the minimum you'd be likely
to see in real life.

Have a look at Arnie Coro's great page. You'll find it at:

http://www.radiohc.org/dxers/

He's got lots of ideas for home brew stuff.

Good Luck,

Pete

Yagi's for 1.2ghz are fairly small.

Helical are managable.

Did you want directional or omni ?

John,

All you may need is a base loading coil for the 12 meter band which should
give you a good enough match to 50 ohm coax.

Download program BOTLOAD from website below in a few seconds.

Program will tell you coil inductance, number of turns of what wire
diameter, to wind on your choice of size and shape of coil former.

If you want an even better match, download program ENDFEED which will tell
you values of coil and capacitor for an L-match. Or a T-match.

To design coils for a given inductance download program SOLNOID2.

Hi Charles,

> FYI I have added a line of text to the homepage that states the "
>site is optimized for use with IE 6 " .
This serves only to enlarge the hegemony of Microsoft and is not in
and of itself really necessary to the interchange of HARD information.

As for compliance to HTML, that has hardly changed in years, and for
good reason: it did well what it purported to do for "hyper-text."
What you ascribe to it are the multitude of variant "Plug-ins."

None of this is inevitable, none of this is the shrug your shoulders
with the arrival of new standards. I have done several thousand pages
and all work with Netscape 3 (if not 1 or 2 and IE too). The
stumbling blocks are with "features" not data.

I would add, however, that Netscape has certainly shot itself in the
foot with the introduction of version 6. That was an absolute loser
from the click of the icon. Version 6.2 is vastly better, but still
exhibits puzzling behavior about 10% of the time; but for me, a rather
abusive and demanding user. Internet Explorer has its own similar
puzzling behaviors, and I always get a kick out of it crashing at
Microsoft sites where Netscape sails through.

Like VHS vs. Beta, IE has no technical superiority. It has climbed to
the top out of simple inertia of being installed in Windows. For
issues of compliance I would suggest if the site cannot be viewed with

Netscape 4.7 (still available I believe, and their best version), then that site designer has added a feature that is single sourced, a true indicator of future extinction. Do you write VRML? If you did, you don't now. Once the bright-eyed promise of the Internet, and I doubt one in a thousand readers here know the acronym or even heard it.

Without actual pattern and efficiency information, a guess is the best
anyone can provide. I'd guess about 180 - 220K would be a reasonable
estimate.

Hi Bill,

Well that was my hot button (Java) that got pushed.

Java apps are rare and few on the net. I seriously doubt you have
ever run one -but this is more semantics than experience.

Java comes in two variants: Applets and Applications. Apps is
shorthand for Applications in my world, thus the immediate response.
Applets constitute the greater part of Java exposure to all here.

Then there is java script, an abomination of both Netscape and
Internet Explorer and the origin of the statement about being
"Optimized for IE/Netscape," and what Charles mistakes for being an
issue of standards (the oldest joke on the net starting with IE1).

Java Applets and Applications cannot break your machine, nor can they
snoop nor reveal your machine's data - unless you grant them express
permission. This is, of course, 180ï¿½ around from the Microsoft
security model. For Microsoft products, you have to explicitly demand
such activity not be allowed.

> all bets are off.

This is really a function of the antenna beamwidth. The relative noise contribution of any noise source is a function of how much of the antenna beam "sees" the noise source.

For a relatively broad beam antenna, like a horizontal dipole for instance, the sun occupies a small portion of the antenna's total beamwidth, so it is not that significant. For broad beam antennas, ground noise contributions are generally more significant.

For narrow beam antennas, like satellite dishes, the sun being in the main beam is a real problem and "all bets are off".

Some have guessed that there may be other pics and found them. If you are interested, they are linked of a page that pulls it all together:

http://www.owenduffy.com.au/electronics/post.htm

The notes provide more detail of the earthing treadment.

Re the comments about equipotential bonding, the earths are bonded in accordance with AS3000 (standard for electrical installations) and AS1768 (standard for lightning protection).

Conductors that might take a significant portion of a lighting down-current are 25 sqmm or 35 sqmm, and equipotential bonding conductors are 6 sqmm. Conductors here are rated on their cross sectional (conductor) area, so 35 sqmm is a little over a quarter inch diameter copper.

GDM's were very useful before amateurs thought about selectivity, when
you didn't calculate accurate coils and were pleased with a tuning
capacitor between 50-300pf for the desired band

But, I must admit, I have two models, one is Tradipper and the other
is an old Philips (with two grids - 12AT7 - and neon indicator)

Source record: 150861

Should work great for a multiband antenna. I use the same thing
pretty much, 140 foot dipole at about 30 feet, fed with plain old
TV-twin-lead. Seems like a beam! I work DX effortlessly. Sure, there
theoretically could be a little more loss when it's wet, but I've
never noticed it. If it's raining hard enough to be a problem,
you don't want to be on the air anyway since there must be
a hurricane outside!

I run QRP most of the time. Someone said it only lasts 2-3 years?
Why? Mine has been up more than 5 years, no problems. The twin-lead
I'm using is thick stuff, made for UHF. It's more rugged looking than
the real thin stuff, but still, it's just Radio Shack stuff.

Works fine.

I am planning to do some backpacking this year and will be taking a K1 with autotuner. I plan to use a 102 foot flat top fed with about 30 to 40 feet of TV twinlead. The aspect of weight and size is important. I am trying to decide if a balun is worth the effort and what type I will use. I have a copy Jerry Sevicks, "Building And Using Baluns". If I were to use a balun I am leaning towards a voltage balun.
My main question --- is a balun in this situation really worth the effort versus just feeding the twinlead directly to my autotuner? What will be gained with the balun?

You can use a length of twisted-pair between the antenna analyser and the "grid-dip" loop. Operation is exactly the same. But operating convenience is even better than the old fashioned genuine grid-dip oscillator. Frequency accuracy, of course, is 50 times better.

PS. It's time the selling price on these gadgets was halved. There's nothing very special inside them.

It'll be difficult to make a balun that will work well over the whole range of impedances you'll encounter on the various bands. Working without a balun means that you'll get some feedline radiation. But with low power and away from an urban environment, and considering that the pattern from the antenna will change with band anyway, the added vertically polarized radiation is as likely to help as to hurt. So I'd try it without the balun. You might find that the tuning changes as you grab or move the rig or feedline around. That's because the feedline and rig are part of the radiating antenna. If it's particularly bad on one or two bands, you might be able to moderate it by fiddling with the feedline length. It's this kind of thing that a balun prevents, but again, it would be hard to make a balun that really works well for that antenna. Keep the feedline well away from anything wet or lossy.

I don't know of any situation involved with feeding an antenna where a voltage balun is desirable. Why were you considering using one?

Ditto. My antenna was fed with the cheapest Radio Shack
twinlead money could buy -- we set it up just to try it, and
it stayed there for 13 years!!! I took it down when I went
to a vertical system, and used the twinlead to make a folded
marconi which a chum has been using on 75 meters for the
past 6 years. I never noted any deterioration of the
twinlead, and if there were any losses when it got wet I
never noticed. I had nothing but success with that antenna,
and got consistently good signal reports.

986. Coil Losses vs effects of whip swaying in the breeze

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-15 01:08:49 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <SdL08.26030$V55.2317497@e3500-atl1.usenetserver.com>
Source record: 150774

Here's something for the experts to comment on. All of us know that there are a certain amount
of coil losses in any loaded whip. To minimize that, we can try to run as long a whip as physi-cally possible. Yet, the longer the whip, the more it tends to flop around in the breeze--some-
times causing SWR to fluctuate wildly. So, which would be worse overall: the extra coil losses
with a "stiff" upper whip (with apologies to our British friends), or the SWR created in a Hi Q
coil by a whip thrashing around in the wind?

Doc? CAM? (I tend to think the constant coil losses would be less of a problem than the floppy whip).

Well, in Jerry Sevick's book on baluns he mentions using one for such an antenna. That is the only reason I bring it up. I was leaning towards no balun and moving the feedline and rig as little as possible.
Thanks for the input.

+AD4-The velocity factor for the radials buried 0.1 meter is
+AD4-apparently about 0.2, making them a half wavelength long. By
+AD4AKg-shortening+ACo- the radials from 8 to 6 meters, the loss was reduced from
+AD4-11.9 dB to 5.0 dB, a 6.9 dB improvement.

Gee, then it seems like we should +ACI-tune+ACI- the radials to be electrically 1/4 wavelength in the particular VF they are in. Maybe by tuning the length of the radials to get the maximum current in the radials.

I believe I have both. I use the VHF side of the diamond x-50 and am very satisfied. I have the cushcraft yagi(ar-270 I believe or is the dual band yagi called something else?) dual band and hate it. You could have it (figure of speech) if you would climb the tower and take it down. Now I have had the Cushcraft Ringo Ranger and have been satisfied with it so I am not really against Cushcraft in general.

Cross-posted to: alt.ham-radio.marketplace,rec.radio.amateur.antenna,rec.radio.amateur.equipment

Please contact me via email: robfult@carolina.rr.com

Selling a Hustler 5-BTV Vertical (80-10m) in the box w/ hardware and instructions. I got this from AES with the assumption that it would work well in the attic horizontally. After assembling, it didn't fit well so I moved to Isotron antennas. This is a BRAND NEW antenna -- receipt will be included from AES, purchased 12/31/01. Paid 149.99 -- will let it go for 110.00 OBO.

I also considered a B&W AS-40 which is a 40-10m trapped Dipole Antenna. Paid 154.99 -- will also let it go for 110.00 OBO. The wires have been cut and permanently attached to ONE SIDE ONLY. Wires are cut with AT LEAST 12 inches of "play" for tuning. I attached one of the sides as instructed and decided to go the Isotron route after evaluating the size of the attic.

Both antennas are brand new with receipts -- never transmitted. Original packing, receipt, instructions, hardware, etc is included. Thx!

Lesson learned :)...

thx.

Jerry,
The 'coil' losses are constant. The rate and amount
of change due to antenna swaying is a variable which can
be controled to a large extent. If you have the choice,
longer whips are 'better' than shorter whips.
'Doc

Ps - Where do you get this 'expert' stuff?

Then there is the HamTrans e-mail list- too bad folks
didn't participate enough and it died. I tried to
resurrect it, and it died a second time.

hamtrans@qth.net was a great idea- traveling hams
would post their itenerary, buyers would post their
transportation needs, and if two folks got together,
it worked great!

Last week, I could have carried goods from South Carolina
to Atlanta, GA on a flat-bed for any ham who would have
been interested. I even had a little room on the way
back. But- with the hamtrans list gone, who would have
known?

If anyone wants to start the list back up, go ahead.
I tried and it didn't work.

>
The multiband tuner was an interesting development. They covered all of the then-ham-bands from 80 thru 10 without bandswitching. As I recall there were two models: MB-40 and MB-150 (the number indicates maximum watts)

I think National held a patent on them.

They had a couple of problems, though. They took up almost as much room as a conventional pi-network. You had to be careful that you didn't tune up on a harmonic. You couldn't de-tune to reduce drive without risking all sorts of harmonics. And when used with a heterodyning rig, there was always the chance that a mixing product would hit one of the unused resonances.

I don't recall any manufactured ham gear that used them.

1001. ISOTRON 160 meter Antenna? How well does it work?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-15 07:12:50 UTC
From: Mike Jordan <mjordan@europa.com>
Message-ID: <3C43D672.4050904@europa.com>
Source record: 150789

I don't have the room to run a 160 wire antenna where I live so I've been looking at the Isotron 160 meter antenna so I can get on 160. I know that with an antenna of this type it's going to have a narrow bandwidth, but I have the automatic antenna tuner with my ICOM 745 and turning across the band shouldn't be a problem. But what I was wondering was how the antenna worked other wise? I've done some searches on the internet and I've found some messages of this and the Isotron's for the other bands, but mostly what was said was that they worked.

My main interest is to be able to talk on 160 in the range of about 250 miles between myself and my dad over in Walla Walla, WA. If I can get out further that's even better. Has anyone used or is using this antenna and if so, how did it work? How high did you have it and did you need to ground it to quiet it down (I saw one message that someone had to do this)?

Cost wise it seems to beat buying a vertical that has a 160 meter option and with it's light weight I should be able to get it up higher than I would with a vertical anyway.

Any information would be appreciated.

Thanks

Mike

I'd rather have the longer whip and lower losses anyday. I can deal with the SWR. Actually, this has never really been a problem for me. Sure, I see changes, but it's nothing I can't tune out easily on the fly. I use a tuner for impedance matching. If I tune up in the driveway near my tree, it causes changes, so I'll have to retweak it as I get moving. Once I get out in the open, and tune it in the "flopping backwards" position, I don't have to touch it again. And my SWR stays low. The only time I seem to have problems is around overhanging stuff like trees, etc. But I'm not sure by what you mean as a long whip. My present one is about 7 ft above the coil. The top 5 ft of that 7 is thin springy whip. There is one exception to this though if you think about the whole whip. It's better to have mast below the coil than above it, up to a certain extent where the coil losses start eating you up. So if you take this train of thought, a short whip would be fine if you had a long mast under the coil. If you had two antennas with a total mast of 8 ft plus a foot for the coil with ground losses of 6 ohms, and one had a 2 ft mast + 3 inch coil + a 6 ft whip, it would have an efficiency of about 7.5 %. If you used a 6 ft mast + coil+ 2 ft whip, you would have about 12 %. "this according to Reg's vertload program". So really it's better to have the short stinger and a long mast, but of course if you are like me, you get the long mast going but get greedy and decide to use a long stinger also so you can really get with the program. :) I just deal with the SWR changes using the tuner. I'm in the process of cooking up a 160m mobile antenna. It won't be a barn burner being so small, but should be usable at times I hope. That will give me all bands 160m-70 cm mobile. "Cep't for 220 mhz."..I still can't see why icom left that band off the 706..Seems to me it would be fairly simple to have included it, but maybe I'm missing something. With the ft-100, I hear 220 works as far as rcve but it won't transmit..MK

I'd be interested in the method used to obtain such precision. What
happens on a warm day?

I believe there is information on such systems in the Antenna Compendium
books. They should be listed on the ARRL site.

I use cheap 300 ohm ribbon to feed a 66 foot dipole, half of which is supported under the eaves of the house. The rest of the dipole is supported by trees. I usually get good signal reports on all bands

from 40m to 10m using just 100W from a FT102 into a MFJ tuner.
Working DX also seems to be no problem. I have also not noticed
any problems with operating whilst the feeder is wet.

Source record: 150796

Hello,

I am hoping that the great wealth of antenna expertise in this NG can help me with this problem :

I have built the Ramsey Electronics AM-25 synthesized AM radio transmitter. The power is 100 mW at 1350 KHz.
Following the manucfacturer's recommendations, i use (indoors) a vertical length of 6ft of insulated wire as the antenna, loaded at the bottom by a 350 micro Henry coil. The coil is 190 turns of enamel magnet wire randomly wound on a 1.5" diameter PVC tube 5" long. There is no variable capacitor either in series or in parallel to "peak" the antenna. The transmitter output has a double Pi filter output filter (3 inductors/6 fixed caps). The inductors and caps are selected in a table given by Ramsey according to output frequency.

The transmitter works well BUT :

I get only about 150 ft range which i think is not much considering the 100 mW power. The transmitter is in a non-metal building appartment on the 5th floor and i went in the street below with various AM receivers. I loose the signal about 50 ft away from the building/

Receivers near the transmitter exhibit hum, even when the transmitter is powered by batteries !
The hum is dependent on position in the room and sometimes cancels out. Do i need a ground ?

I tried measuring antenna resonance by approaching a transistorized grid-dip meter, but can find no resonance. When used in the field strength mode, the meter shows radiation a few inches away from the loading coil but not along the antenna.

My conclusions so far :

- The antenna is poorly matched because the loading coil is either too high or too low in value, but how can i measure resonance if the grid-dip shows nothing ? should i insert a variable cap in series with the antenna at the transmitter output ?

- I probably need a ground (difficult in an appartment with out of spec wiring).

What is your advice ?

Thank you very much in advance for your recommendations,

Best Regards

Ham Radio University 2002/ARRL New York City-Long Island Section Convention

Ham Radio University 2002 for Long Island

North Babylon, New York - On Sunday, January 20, 2002 at 8AM, the doors of the Babylon Town Hall Annex on Phelps Lane will open for the third annual Ham Radio University. Ham Radio University 2002 is a day of education about Amateur Radio.

This year the forums have been expanded and new forums have been added. There will be twenty, one-hour presentations with special forums geared to the non-ham as well as the experienced ham radio operator. The focus will be "hands on" with many demonstrations.

Come join us at the Babylon Town Hall Annex, Phelps Lane, North Babylon, Long Island, and learn about everything from satellite communications, low power operating using radios as small as a tuna tin, how to put up an emergency antenna, the latest information on advanced digital communications, finding and fixing radio frequency interference problems to purchasing your first station equipment or handi-talkie and a special "Ask the Experts" forum. There will also be a Special Event Station W2V set up and operational on HF. There will live SSTV pictures uploaded to the NLI WWW during the event.

HRU 2002 is sponsored by the Great South Bay ARC and is a cooperative effort between over twenty clubs and organizations in the New York City- Long Island area. It is also the American Radio Relay League, New York City-Long Island Section Convention. Besides the forums, there will be tables set up with information about the different groups, ham radio classes, exam session schedules, public service and other activities.

Join us for a day of fun and education for the whole family!
Admission is open to all - donation is $2 per person.
(complimentary refreshments available)

For more information contact:
Phil Lewis N2MUN, Chairman, n2mun@arrl.net or call 631-226-0698
George Tranos N2GA, ARRL NLI Section Manager, n2ga@arrl.org or call 631-286-7562

It's much easier to shunt feed it leaving it grounded. There is lots of info out there. Many towers are used that way even on 160 meters. If you have a lot ot aluminum in the air above it that adds capacitive loading and helps lower the resonant frequency.
L B Cebik's website should have information.
.

You complicate the project considerably by your requirement to switch the netork in and out without leaving the drivers seat (if I understand correctly). For base station use a homemade trap would serve this purpose well, but would be unwieldy on a mobile whip.
You can use a ten meter Pro Am whip and change to a longer "stinger" for 12 meters. Or use a 12 meter whip and change to a shorter stinger for 10. You can use some older CB antennas and rewind them to use on the higher HF ham bands. I once did this for 17 meters and worked all over the world with an Icom 735 running 50 watts mobile.

Mike, if you use an Isotron on 160 you'll just *think* you're on 160.
You won't work anyone outside the neighborhood. It's almost as bad on
75/80.

>
HI Larry & Roy,

I've used in the past the method Roy is talking about and it works real
well,, there may be a need for seperate tuned radial on one or more bands to
keep rf off the rig, I found the CW keyer was easily impacted by rf
currents and can make for some funny sounding Morse on CW. I would think
that a well thought out real windom antenna with single wire feed may also
be a viable backpack antenna setup..
one other issue that may need to be looked at is that most internal tuners
are not vary wide range in the 80m & 160 meter bands. Anyway it's food for
thought.

Shunt feed the tower, or use the whole thing as a folded monopole.
That way the tower could be grounded.

If you are using a balanced antenna with balanced feed line, why do
you need a balun? Does your tuner already have a balanced output?

At the power levels you are talking about, you could wind a balun on a
1" toroid. Even better...wind a few feet of the feedline into a coil
a few inches in diameter. Something like this has been in the ARRL
books for several decades now.

Couldn't you give us another decimal point?

This reminds me of when H-P gave the ARRL lab an 8970 noise figure box. The lab did some product reviews and spouted the NFs to two decimal place precision.

I once tuned up a 1296 MHz preamp for a friend. We measured 0.7 dB NF. Then I put it on the (scalar) network analyzer and measured the mismatches (~ 10:1) and did the uncertainty calculations.

His NF was 0.7 +/- 0.6 dB. So as Rich Measures would say, "The Nearly Perfect Amplifier."

From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c44a0be_1@news1.prserv.net>
Source record: 150725

Group:

There have been a couple of mentions of the folded unipole for AM broadcasting in Broadcast Engineering recently, but the technical information given on design is a little shallow and incomplete. Has a rigorous analysis of this design ever been published, and if so where? It doesn't seem to show up in IEEE or any of the broadcast related technical publications. Apparently it came along since LaPorte, and neither Kraus nor Jasik treat this particular configuration. Even a good method of moments analysis using NEC by a third party would help.

okay, I got a homebrew ANT switch box (1 to 5 with the option for a 6th) the Input/output connector is SO-259 with 3 SO-259 and 2 screw terminal blocks for connecting. My MFJ259 swept it has good for 20 meters thru 160 meters(less than 2:1 on 20 meters and flat on 160 meters), I only have a tech lic (KB9YMX) and can't use HF so I'm getting rid of it. Pic's on request and will answer every question I can.

THIS IS NOT MY NORMAL ACCOUNT.... (I'm at school right now) ... I can be reached at Tazanator1@attbi.com I trade under tazanator on ebay for referances (27 as of this morning).

> --

Remember the loss in dry ladder line at HF is primarily due to the
series
resistance in the conductors. Let's say the feedline is an eighth
wavelength
or so in length, a reasonable value for the urban ham with space
restrictions
on the 160m band.

Suppose the termination is 45 ohms resistive, the SWR is 10:1 and the
transmission line losses are near maximum due to the high current
everywhere
along the line.

Now suppose the termination is 4500 ohms resistive, the SWR is still
10:1 but
the losses are now significantly _lower_ than if the transmission line
were
matched because the currents are so low.

Do you still trust your calculations?

Can anyone out there explain why a "diplole" center fed with twinlead can be tuned for any band (with a tuner) and how that's different from, say, putting an old boxspring in your tree and tuning that for any band?

Is there something special about the length of the antenna and feedline and, if so, what is it?

Hi Jerome ,

I don't know what your government restricts antenna size to for this low powered AM service, hopefully it is not limited to 2 meters. If that is the case, so be it. However, you could drop a ground wire from your 5th floor (being clever to hide it - and even if it did not touch ground) and find your coverage boosted considerably. The problem is in the efficiency of the short antenna (= none). The addition of inductors, capacitors, in any combination is unlikely to bring much reward when what you need is size.

You would do well to review past postings to this group about 160M Antenna characteristics, especially those wanting to use that band mobile (and thus revealing the huge losses that must be suffered).

Thanks chaps,

I have a 33ft glavanised steel box section telescopic tower
I will have a look at the ARRL website to see what's available.

Incidently has anybody had any experience of using E/H field antennas?.

Yep, the 0.05dB is the estimate for the losses for *100 ft* of ladder-line
on 160m. 100 ft of ladder-line includes a current maximum point when
the feedpoint impedance is the estimated 6-j1400 ohms for a 102 ft
dipole used on 160m. Since 100ft of feedline doesn't include a current

minimum point, it looks like I *underestimated* the losses due to SWR.
In my original response, I should have said, "Assuming a matched line
loss of 0.05dB/100ft." Sorry I omitted the 100ft parameter.

> if so, what is it?

Any SWR circle on the Smith Chart crosses the purely resistive line at a point where the purely resistive impedance is less than the characteristic impedance of the transmission line. For dipoles at least 3/8 wavelength long, that purely resistive point is a good place to feed the antenna system from the transmitter since that pure resistance is usually between 25 ohms and 100 ohms yielding a 50 ohm SWR of 2:1 or less. The thing responsible for the transformation of the antenna feedpoint impedance into a relatively low pure resistance is the transmission line, e.g. Z0 = 300 ohms in the case of the G5RV.

The G5RV is 3/2 wavelengths on 20m and is fed with 1/2 wavelength of 300 ohm line.

On 20m, the antenna feedpoint impedance is close to purely resistive and transforming that resistive impedance through 1/2 wavelength of 300 ohm line yields an impedance that is close to resistive and easy to match.

On 40m, the antenna feedpoint impedance is highly resistive and highly inductive. 1/2WL on 20m = 1/4WL on 40m so the 300 ohm matching section transforms the high feedpoint impedance into a low impedance relatively close to being purely resistive and is easy to match.

On 80m, the antenna feedpoint impedance is low resistance with a component of capacitive reactance. 1/2WL on 20m = 1/8WL on 80m so the 300 ohm matching section transforms the feedpoint impedance into a low impedance relatively close to being purely resistive and is easy to match.

A similar thing happens on 12m where there is an easy match. The match is not as good on 15m but is still acceptable.

The 1/2WL on 20m length of 300 ohm line turns out to be a terrible choice for 30m, 17m, and 10m where the G5RV is predictably, a poor performer.

There is something special about the length of the matching section but, unfortunately, it is not special on all 8 HF bands.

Good afternoon all

I have a question. I have a deep fringe VHF/UHF/FM directional antenna.
Its about 6 months old and has suffered ice/snow damage.
My question is has anyone heard of anyone that has or sells replacement
elements for these antennas or even just the bulk aluminum tubing to cut
to size and fabricate?
I would lke to save this antenna if possible.
All help would be greatly appreciated. thanks

List,

I apologise for the repost, but so far no response.

I have acquired a National RJX 1011D txcvr.

However I have no details with the unit at all, I desperately in need of the microphone pinout details as the unit has no mike, and also a good readable copy of the tuning details, perhaps the full operators manual.
I will pay for a good copy etc

1034. Re: BALUN or NO BALUN???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-15 20:36:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C4492DB.1DF4ED3@eznec.com>
Source record: 150721

Feedline radiation is caused whenever the currents in the two conductors of the feedline aren't equal and opposite. Using a symmetrical antenna and symmetrical feedline like twinlead don't guarantee this. If you connect one conductor of your "balanced" feedline to the center conductor of your rig's antenna connector and the other to the chassis, you're just about guaranteed to have unbalanced currents in your feedline. Your rig produces equal and opposite currents on the center conductor and on the inside of the ground part of the coax connector. All the current from the center conductor flows into one conductor of the feedline. But the current from the inside of the ground part of the connector splits. Part goes into the second feedline conductor, and part flows over the outside of the rig to ground however it can get there. Exactly the same thing happens at the antenna end of the feedline if you connect coax to a dipole. The amount of imbalance depends on the relative impedances of the two available paths for the ground or shield current. Either twinlead or coax can carry balanced currents and be balanced, and either can carry unbalanced currents and be unbalanced. Using twinlead doesn't help current balance in any way.

Tuners with a "balanced" output usually have an integral 4:1 voltage balun. This should work fine if the impedance of the antenna isn't too high and if it's physically symmetrical. The problem is that the impedance of a multiband dipole can be too high on some bands for the balun to work effectively.

To learn more about this, see "Baluns: What They Do and How They Do It" in the _ARRL Antenna Compendium_, Vol. 1.

Robert,
When you really 'get down to it', there isn't a huge
difference. It's more a matter of getting the 'correct'
input impedance of the 'box springs' so your transmitter
will 'like' it. It'll work. It won't be all that 'good'
of an antenna on 80 meters, but better than you might think
above 15 meters. It'd also help if you had two 'box springs',
you know, keep it balanced. If you happen to try this for
an antenna, would you please take pictures? I wanna see
how you get the 'springs' up into the tree...
'Doc

Source record: 150723

Robert,
Joking aside, the G5RV is a 1.5 wave 20 meter antenna with
a fairly odd impedance matching system, that just happens to
work on other bands (with a tuner). The reason for that sort
of matching method is that those components are what Mr. Varny
happened to have on hand. I had the opportunity to ask him,
that's what he said...

Source record: 150724

Jerome,
The performance of your transmitter sounds like it's
about 'normal' for the antenna your using. Aside from
the legality, a larger antenna would give you more range.
From an appartment, you will really have 'fun' using a
larger antenna! Meaning a 1/4 wave (about 180 feet) is
going to be very difficult. You might search for information
about "small, loop, transmitting antennas". I still
wouldn't expect much improvement, but there will be some.
Your neighbors are going to ~love~ you...
'Doc
PS - A ground will improve the performance.

Back to the subject of a voltage balun. In Sevvick's book he mentions some tests he ran and experiments he did with voltage baluns specifically for tuners and dipoles for multi band operation. Any thoughts to his ideas?? I also plan to operate only on 40, 30 ,20 and 15 M bands. i am going to do a little experimenting myself to come up with a dipole and feedline length to cut down on impedence excursions as much as possible. Interesting topic, to me anyway.

Texas Towers www.texastowers.com sells raw aluminum tubing, and probably some of the other antenna shops in your part of the country do also. One trick we used to do is to visit an antenna installer and buy a couple of old busted antennas for the tubing. If there are only a few breaks, splicing them becomes cheaper than replacement. Use stainless sheet metal screws wherever possible.

In the USA, the "Toy and Model" stores sell a variety of
small aluminum and brass tubing. So does a hardware
store chain known as OSH (Orchard Supply Hardware).

Good luck -- Mark

I'm sorry, I haven't read the book mentioned earlier. In his "Transmission Line Transformers", he presents many measurements which I fully believe are valid, but I've gotten the distinct impression that he doesn't really quite understand what the purpose of a balun is in the first place. I put my views forth quite a few years ago now in the Compendium article, and have seen no evidence since that any of what I said there is incorrect. In that article I explain how:

1. The purpose of a balun used in feeding an antenna is to prevent common mode feedline current, and therefore feedline radiation.
2. Common mode feedline current is the vector sum of the two conductor currents (or half this value depending on your definition), so common mode current is zero only when the conductor currents are equal and opposite.
3. The "current" balun (a term I coined in that article) is one that forces the conductor currents to be equal and opposite, which is what a balun needs to do when used with an antenna. A current balun can also be appropriately called a choke balun or common mode choke.
4. A "voltage" balun (also coined in that article) is one that forces the conductor voltages to be equal and opposite relative to the "cold" side of the balun input.
5. If the antenna is entirely symmetrical with respect to ground, the third winding in a 1:1 voltage balun conducts no current. It can then be disconnected with no effect. The result is identical to a two-winding 1:1 current balun.
6. If the antenna isn't entirely symmetrical with respect to ground, a voltage balun will CAUSE common mode current to flow by attempting to balance the conductor voltages.

So at best, a voltage balun will work as well as a current balun. At worst, it'll increase feedline radiation. At the time that article was written, nearly all the commercial baluns were voltage baluns. I'm glad to report that this has changed.

I'd like to note that there is a place for voltage baluns, in feeding voltage driven push-pull amplifiers, for example. But they're not the thing to use for feeding antennas.

I highly recommend the analysis of balun operation at http://fermi.la.asu.edu/w9cf/articles/balun/index.html.

A folded unipole is nothing more than half a folded dipole, which you'll find discussed in just about any text, such as Kraus, Jasik, or Johnson.

I have used both the Kiwa and the Terk extensively. The Kiwa is not worth the money. The terk is as good as it gets, unless you roll your own---but make it big.

Greetings!

I'm researching a circa 1943 Silvertone Mod. 7051 console radio. The schematic refers to a loop antenna, but there is none. There is a sticker inside the cabinet that refers to a "Radionet Self-Contained Aerial System". There are also a bunch of short reddish strands of wire/cloth remnants throughout the inside of the cabinet. Is this some kind of antenna 'fabric' that was used at that time? Anyway to replace it?

TIA

Steve

-- I drive a full size van for work and I want to install an HF rig and antenna. I currently have a President HR2510 and a modified K40 mounted on the roof. It works fine for 10M. I want to install an ICOM 706MKIIG. I have a hustle but I am concerned that it would be too close to the van body if I mounted it on the driver side bumper and even worse if I attached it to the side panel. What are other hans using and where have you got them mounted. The roof is not an option as I sometimes go into areas that are height restricted.

Thanks

John

First, let me invite you over to rec.antiques.radio+phono where someone might be able to help more than I.
I have a large table model 1581 that has all the jazz about the Radionet on its back panel. The Radionet antenna itself in this model isn't much more than a glorified loop antenna, in my case about 12" square. Since its a multi-band SW set there may be some windings specific for BC and SW but I really haven't attempted to sort it out. I don't know if Silvertone used the 'Radionet' term in a generic sense but it wouldn't be a surprise.
If you don't have the schematic, you might want to check http://www.nostalgiaair.org click the Rider's Online link and see if its there and if it depicts anything notable about the antenna on the schematic such as separate windings, etc.
One like mine would certainly be re-creatable, so if you need any specific info re turns dimensions, I'll be happy to provide them.

Regards,
Bill WX4A

If they're crimped aluminum rod elements like a typical TV antenna.. its pretty easy to install wood dowels of proper size into the bent elements and re-form the aluminum around. If the whole thing is bent up bad, you'd probably get off cheaper to replace it. Real Aluminum Tubing isn't cheap.

1049. Re: BALUN or NO BALUN???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-16 00:58:04 UTC
From: tdonaly@cs.com
Message-ID: <20020115195804.22706.00001878@mb-mi.news.cs.com>
Source record: 150737

In the third edition of Jerry Sevick's book,
Transmission Line Transformers, starting on page 9-3 he writes,
referencing a schematic of a three winding Ruthroff balun,
"The third wire, winding 5-6, according to Ruthroff's 1959 paper, is
necessary to complete the path for the magnetizing current (ref 9).
From recent discussions with colleagues, including Ruthroff, it was agreed
that the third wire is not necessary in the performance of his 1:1 balun
in antenna applications. When the reactance of the windings is much greater
than RL (at the lowest frequency of interest), then only transmission line
currents flow and the magnetizing current, as such, is irrelevant."
He goes on to enumerate the disadvantages of using a three-winding Ruthroff
balun for antenna use.

Later he writes;
"On the other hand, the Guanella 1:1 balun shown in figure 9-3, which is
nothing
more than a coiled bifilar winding, does not have the negative effects of the
Ruthroff balun." He goes on to say why he thinks so.

For those who want to know Jerry Sevick's opinions on baluns for antenna use,
chapter 9 of the third edition of his book is a good read.

Someone out there is going to laugh at me, but at my age, I don't care. If you have a 10mtr whip already, is it not possible to get one of the old telescoping whips for a CB portable, lash it to the top of the whip and then extend it when you want to operate at 12mtrs? I know this sounds like real "amateur radio", but what the heck, that's the way the hobby goes. :-)

BTW, for the purest, let's not worry about a return loss of 10 db versus 14 at the desired freq. Let's get on the air! Keep that Poynting vector pointing in the right direction. E X H, rah, rah, rah! :-)

Thanks very much for bringing my attention to Chapter 9 of Sevick's book. I had looked at the first edition of his book in considerably more detail, but haven't looked much at the second edition. It was that and some of his other writings that made me think he didn't understand the function of baluns when applied to antennas. In the second edition, he's completely revised this chapter, and agrees that a current balun is the preferred implementation for antenna applications. So he has figured it out -- I stand corrected. I'm glad to see he's carried this on to the third edition, which I don't have.

Now, can someone please explain to me exactly what it means for the third winding on a voltage (or Ruthroff) balun to "complete the path for the magnetizing current"? This is the only explanation Ruthroff gives in his paper for its existence, and Sevick uses exactly the same wording without further explanation. Of course, what it actually does is force the voltages to be equal and opposite through conventional transformer action. But what does this have to do with magnetizing current? The only use of the term I'm familiar with is the current that flows in the winding of an unloaded transformer. It can be made smaller by making the winding inductances higher, and is generally considered to be undesirable. Perhaps he explains this in the third edition?

Ah, but there's the rub, Roy:

The specific configurations being discussed aren't pure folded monopoles. Several variations include multiple down wires which may even be individually fed by multiple transmitters on different frequencies, the fold may or may not be at the top, funny things (well, reactances in peculiar configurations) appear at the bottom as part of the feed, and so on. The early A&P articles may well be what I am looking for, as I didn't search back that far. The BE articles intimate that the design is much newer than that. Folded unipoles at VHF I know from the 1940s Andrew designs for two-way radio, (I think there is still one out in the antenna boneyard somewhere) but this is more involved, or at least that is what the broadcasters try to lead one to believe.

I'm sorry. I read your posting too rapidly. From the context, it sounded like "this design" was referring to folded monopoles in general, rather than to a specific design. I don't subscribe to Broadcast Engineering, so don't have any idea what the design you're referring to looks like. Based on your brief description, it sounds like something that NEC could probably handle. Have you tried contacting the author of the article?

Thanks, Doc, but unfortunately the windows aren't the jalousie type
with the narrow panes. I had that once before and just used a piece of
wood or plexiglass like you suggest. These awning types that are
common in SoFla are about 18 inches wide and four feet long, with
rubber seals. A pain (sorry about the pun) to replace.

Thanks, Dennis

The coax is buried coming up to the exterior wall and the station is
just inside the wall, so I am hoping to make a direct path through the
wall rather than up and down. Also, I can seal it tight that way with
silicone or caulk. I had to take down a dipole that I fed through the
attic vent and down the wall. It was tied to trees and a million ants
followed the feedline into the house and made a home in the wall. Took
the exterminator months to kill them all! We have all kinds of creepy
crawlies down here and they seem to find every entry into the house.

Thanks for the feedback and suggestions. I was looking at all the boxes at the home improvement warehouse store and kinda liked the weather-tight outlet boxes. Are there boxes like that made just for coax?

Thanks for the drilling, tip, too. The inside wall is finished sheetrock so I am not too concerned about that, as I can put a box or plate there, too, I think. Any suggestions as to how to avoid connecting with existing wiring in the wall. I will shut off the breaker to the outlets, of course.

Source record: 150759

Actually, there isn't an easy answer to the question, and EZNEC can't answer it. Asking for the impedance at one end of an antenna that's 60 feet in the air is exactly like asking what the resistance of a one-leaded resistor is. You can't connect to a one-terminal resistor, and you can't connect to a one-terminal antenna. Ultimately, you've got to have a return current equal to the current going out. And the path it takes represents an impedance in series with the antenna. For example, if you connect a piece of coax to your rig, a current flows on the center conductor and an equal and opposite current flows on the inside of the shield. At the other end of the coax, suppose you connect the center conductor of the coax to the antenna and leave the braid disconnected. Whatever current flows to the antenna has to be matched by an equal and opposite current on the inside of the shield. The only place for this current to go (or come from) is along the outside of the coax. So the impedance along the outside of the coax has as much to say about how much current flows into the antenna as the antenna itself does. If you put a current balun at the feedpoint to choke off the current on the outside of the coax (or the path to ground along the outside is a quarter wavelength), it'll act like the coax is open circuited at the end. The coax will see a high impedance, regardless of what kind of antenna you hook to it.

For either a person or a program to answer the question, it's necessary to know exactly what the feed system looks like. The feed system is just as much a part of the radiating antenna as the part you think of as the antenna. It has at least as much effect on the impedance as the "antenna" does. The feedline is the other lead of the "resistor".

> Please tell me what is correct answer and why?
====================================

a) is correct, but -

Doubling diameter increses bandwidth by an almost imperceptible amount. So forget it. Diameter has to be increased a hundred fold, or much more (from thin wire to fat cage), to have any useful effect on bandwidth.

Considered as an LC tuned circuit, capacitance increases by an almost imperceptible amount and inductance decreases by an almost imperceptible amount but the damping resistance, the radiation resistance, tends to remain the same.

So resonant Q = (Omega * L) / (Radiation resistance) decreases with L.

Resonant frequency and velocity factor (1 / Sqrt(L*C)) tend to remain the same.

Gain is relative. Relative to what? Another 1/2-wave dipole? dBd? c) and d) are meaningless.

Source record: 150761

It's not a simple question. It is an impossible question to answer. You
omitted to give wire diameter.

And if the transmitter is at ground level will not the 60 feet of wire in
the vertical feedline entirely change the actual feedpoint impedance and
become part of the radiating system. You will have an inverted-L.

If the transmitter is actually at the end of the long wire, the 60 feet long
connection down to ground from the transmitter ground terminal will still
form a very important part of the radiating system. The input impedance
looking down into the vertical part should be added to the impedance looking
into the long wire.

What do you propose to do with the figures when you have them ?

Try downloading program ENDFEED from website below. Takes only a few
seconds. Use it to model whole system including ground electrodes. Will
also provide L and C values for various types of tuner.

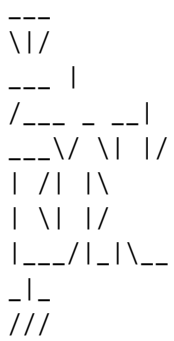
I have always wondered why, when talking about baluns, nobody even mentions the possibility of using a 1:1 (or X:1) isolation transformer at the antenna side of the transmission line. Like:



From a "not knower" point of view it would resolve all the problems of unbalanced currents, no matter wheter the antenna is balanced or not. What are the problems of it? Is it a question of expense/difficulty of building or maybe is that is cannot work as a balun? Please explain :-)

1075. Re: BALUN or NO BALUN???

Roy:

I too do not understand what Sevick meant about that support of the magnetizing inductance by the "third" winding.

Here's my understanding of the terms.

Magnetizing Inductance Lm in the conventional transformer is the very desirable "large" apparent shunting inductance which appears essentially across the input or output terminals of a transformer behind the small leakage inductances.

A large magnetizing inductance Lm is desirable since it extends the low frequency cut-off of the transformer. This is in contrast to the Leakage Inductances Le1 and Le2 which are small apparent series inductances in series with each winding. It is desirable to have the leakage inductances Le1 and Le2 as small as possible since they limit the upper frequency cutoff of the transformer.

Ignoring winding resistances, and self and interwinding capacitances, to a first order, on a two winding conventional transfromer, quick measurements of Magnetizing and Leakage inductances Lm and Le can be made by measuring the open circuit and short circuit inductances Loc and Lsc on a bridge.

The open circuit inductance Loc is the inductance measured across one winding with the other winding open. Loc is approximately Lm+Le. And since Lm>>Le, then Loc~Lm. The short circuit inductance Lsc is the inductance measured across one winding with the other winding shorted, it is approximaely equal to the leakage inductance Le. Measurements of Loc are "more accurate" than measurements of Lsc since the equvalent inductance is of much higher Q and gives better bridge nulls.

I believe, from making many such measurements in the lab, and using them to predict performance, and correlating those results with bamdwidth performance measurements, that my understanding of these terms is correct.

I guess I need to read Sevick again several times to "get" how that third winding works... what?

Guess it is because the FCC sez so. And it might have something to do
with the fact there are
700,000 hams in the USA and about 65,000 in Canada. On 20 Meters - USA
allotment is now 150 kHz for CW/Data and 200 kHz for CW phone/image --
seems fair. One can operate CW in the "phone band" but few do.

I seem to recall the USA phone privileges were expanded a few years
back. About 1987

Thank you for your reply.

Hanging a ground wire outside the front of a building located in a restricted (historical) section of town is not really an option. For ground connection choices i have :

- A water drainage pipe on the balcony
- AC power supply ground 30 ft away in the kitchen

would any of these do ?

Option 2 : lengthen the antenna using fine enamel wire going around the room at ceiling level (about 40 ft) would i need to insert a variable cap in series (value ?) to tune for resonance.

Thank you for your help &

Thank you very much for replying. Don't worry too much about the neighbors, i have selected a free channel frequency, and even at night there is nothing there. The modulation is not driven beyond 80% (scope check) and there is no splatter. Besides, the standard AM band is practically abandoned by the French, in the daytime there are only 5 stations on the entire dial, including the BBC World Service on 648 KHz. Historically, say 40 years ago , France broadcasted mainly on Long Wave, then in 1981 the FM band opened up to commercial service, so the standard AM band was never very occupied over here.

Thank you for your help &

This seems odd to me. All the CW gurus I know say that CW gets thru QRM far better than, say, SSB and my very limited experience bares that out. So, why does a superior signal need special allocations? It seems more logical to protect SSB, etc, from CW than vice versa.

Does anyone know of any monoband antennas for 6m for an HT? I've been told that a 5/8 antenna on 2m is a 1/4 wave on 6m, so could I use a telescoping 2m 5/8 antenna as a 1/4 wave on 6m?

Hi All,
I've got a similar challenge. The exceptions are vinyl ladder line and
very, very strict housing, i.e. no drilling. The house is a pillbox with no
attic and all concrete construction from the foundation to the roof as well.
I'm gonna have to talk to somebody to see what can be done with the
window.

Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew,rec.radio.amateur.antenna

Can anyone please help with any good leads on where to find a table of transmission or blocking properties, (attenuation :vs: freq?), for typical engineering polymers and coatings for polymers (conductive EMC shield paints?).
I'm particulary interested in the 2GHz-7GHz range.
Many thanks in advance,
JB

please excuse the cross-post

Not only that, but you often get YELLED at if you do! Maybe they're just
embarrassed that they don't know CW anymore (or never did).

Message-ID: <3C45AAB1.99BDF57@att.net>
Source record: 150674

I have the same type van, a 1986 Chevy G-20, and installed a 706 as soon as ICOM manufactured the original model. Here is how I proceeded after a lot of thought.

After careful consideration I chose a "Screw Driver" style antenna. "Why get a multiband radio and have to switch coils or sticks...?" were my thoughts. I waited a long time to install a serious mobile rig, let's do it right. The expense is well worth it. Mobile HF has its limitations, especially at the longer wave lengths. Why waste power with an inefficient antenna arrangements.

As the antenna current is maximum from the feed point to just below the center coil, an this is where max radiation occurs. I chose to mount it in a way that the body's effect would be minimal. Drivers front bumper with a special trailer receiver tube welded to the frame worked fine. Actually my antenna is removable from the van and easily installed on the family station wagon, drivers rear position. You do get a few unusual looks, but the antenna works better than I could have anticipated. Remember to pay attention to grounding at the feed point. A good, low impedance ground is a must to the body. I used 1.5 inch copper strap for this. Also watch your height considerations. It is easy to start hitting a lot of overhead obstructions.

I purchased a High Seirra screwdriver and their hitch mount. It work the best for my plans. I guess if I had the time and was not working all day long with RF equipment, I might have built a screwdriver antenna. The real deal is that it is a trade off between your spare time and available dollars.

Best Regards,
Steve Barreres - K2CX

Thanks for making my point. Since their are so many US hams
all the more reason to have a much bigger phone band like
Canada (Phone being more popular of a mode and much
more practical) And I do a lot more CW than phone.
The fact that ham radio is more popular in the US than Canada
is irrelevant.

This is what I did for mounting a vertical antenna, along with
a spare mast for experiments

get a 8 ft long pressure treated 4x4, and 2 8 ft long treated 2x6s

mount the 2x6 sections across one surface of the 4x4, seperate them by about
3 feet.

sink a 4 ft deep hole in the ground with a posthole digger, then stick the
post into the groun. Use U-bolts to attach antenna masts to horizontal 2x6's

see cheesy ascii art for details ... (not to scale)

```

Hi Jerome ,

Adding length to the antenna is in order, only if your government
allows (this goes for the suggested wire dropped out the window too).
Your suggestion of looping it around the room might boost performance
- maybe.

Connection to the drainpipe could do the trick, or to the ground at
the AC supply in the kitchen(?). This would bring the building wiring
into the act as being part of the radiator (until that ground wire
actually hits ground). Either of these extends the radiator
considerably further than may be thought.

You ask about inserting a capacitor, and if it would be effective.
This is something that is best determined experimentally as the local
conditions and variables are such wild cards at this wavelength. It
is very unlikely you will hit on the solution the first time, or
possibly even the tenth time. You have to recall, the whole point of
your kit was to limit broadcast range so as to not to interfere with
licensed sources. With such limitations built in, you may already be
at the limit of what is possible. Frankly, I think those 2 pi filters

(although very necessary) are designed to an impedance that serves to kill most of that same 100 mW. That is, without a matched load (proper antenna) there is a massive SWR at the connector due to the low radiation resistance. That "proper antenna" by law here in the US is impossible to connect to (we have limits to how much height can be used for these experimental transmitters).

Any way you look at it, by either law or design or both, your situation is one of incredible inefficiency - maybe 0.1% at best and probably much worse. This means that from that initial 100 mW, you are probably only radiating 100 ï¿½W (which is still quite a lot, locally - within one block).

I guess it depends on what bands you want to work. The body of the van
can be a problem, and it's always better to mount on top if you can
get away with it. But for low band antennas , this is going to be hard
to do. I'd rather be off the front bumper than the rear if the van has
a short" hood". But it does look a bit funky...Many mount of the rear
bumpers, but the body does lower the performance of the antenna. Maybe
you could mount off the rear panel up a bit with a side ball mount,
but not all the way to the roof. Then use a hustler fold over mast to
get into low places. It's very important to try to keep the coil above
roof level if you can. For the high bands, I'd probably use modified
ham sticks on the roof itself and just let them slap off stuff much
like your K40 does. A roof mount on a van is about as good as it gets
for a mobile antenna platform. I'm sure you've noticed the K40 on the
roof works like a hose. Or should anyway... MK

Are you leasing your home? Is that why you can't drill? I went thru my wall with a couple
pieces of 5/8" hardline left over from a job. I split the ends so that a "barrel" connector would
fit in each end, and burned out the diaelectic with a torch just enough for these connectors to
slide inside the outer metal jacket. I then used small hose clamps to tighten down onto the
hardline "trapping" the barrel connectors inside. After checking for continuity, I slid these thru
the wall and connected the antenna coax and the rig via a short jumper (I drilled a hole, of course!~). Works fine. I own my house and I don't have a homeowner's association trying to
tell me what I can/cannot do with my own property. I'm too independent for that! LOL!

The mike would be simple. Just get a gator clip jumper wire and probe
the pins to ground. When you get one that keys the rig, you have your
PTT hot line. It's possible there may be a floating ground on there
also, but depends. When you find the one that keys the rig, then clip
to the others and just let the other lead float. When you get to one
that produces some hum, that is your audio hot line. Once you find
those two lines, you can check to see if any of the other pins are a
ground. Some just use the chassis as the ground and have two pins.
Some may have 4 pins, and grounds. BTW, make sure your drive levels
are set to low before you start trying to key the rig. You don't want
it keying up with full drive, and having the finals mismatched. :(MK

Also, I probably should have noted obviously you will need to be
listening on a recvr tuned to freq to listen for the hum on the audio
line once you get it to key up. MK

I like to build simple QRP transmitters, which are mostly CW. Whenever I've tried to reply to some SSB station in CW, it's rare that I get a cordial reply. And I go real s-l-o-w, too!

Hi Toni,

The simple explanation is there is no single explanation (nor single device to cover all situations). In part, what you describe is called link coupling. There are also autotransformer connections to tank circuits that do much the same thing. Each has its appropriate application where it works well, if not dominating all other methods, but that does not translate into universal applicability.

The problem is that the marketplace expects a one device solution and that in turn yields a design of maximum application with no optimization anywhere. Your only hope is that this same design does not carry too many downsides with it. One consequence has been the nearly universal adoption of coaxial feed which necessarily enforces an unbalanced configuration. This was all established with the finals' presentation of a balanced transformer output - immediately tied to ground at one side. Link coupling is built into nearly every modern transistorized rig and then discarded with a wire connection to ground (or through the unbalanced low pass filters that follow the finals).

Dick,

Yes it is, I have read a few articles recently and it seems interesting. I
have no experience of using or building them at all, so I was just after
some opinions / experience.
Why are they not good?.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C45E9B8.8243683@eznec.com>
Source record: 150691

If you can make the tranformer truly act like a transformer, it'll do the isolation job. The problems are more practical than theoretical. You have several things to worry about in designing the transformer. One is winding impedance. The winding impedance, in this case, has to be considerably greater than the differential mode impedance. If it isn't, it'll appear directly across the transmission line. If you use a low permeability high frequency material core, you'll have trouble getting enough impedance in the first place, and you'll have trouble with winding resonances. If you use high permeability low frequency material, it's easier to get a high broadband impedance. But if it ever gets too low, you'll have substantial loss and transformer heating. Another potential problem is capacitive coupling between the windings. This will allow a path for unbalanced currents to flow. The impedance of this path has to be high relative to the common mode antenna impedance.

In contrast, the common current balun degrades gracefully. If its impedance is too low, it simply becomes less effective as a balun, but doesn't add a low impedance across the transmission line. Its impedance has to be high relative to the impedance to ground along the outside of the coax (or the equivalent conductor of a twinlead line) to be effective. The interwinding capacitance is absorbed in the transmission line that constitutes the winding. And the transmission line design is inherently broad band.

This isn't to say that you can't make this method work. It just involves different tradeoffs and would be harder to make work well over as wide a range of frequencies as the more common current balun design.

I dunno why. Maybe it's your fist. Seriously, I have CW SW on my PC so I can stick a mic hooked to the sound card over by the rig's speaker just for that purpose. Some fists copy FB ... others poorly. Based on that, I recommend y'all download some freeby CW SW and see how it does with your fist. You might find room to improve.

Keep the faith ...

Chuckle.

I remember the first QSO I had with an SSB station. It was in the late '50s. It was a Canadian station that answered my CW CQ. He said he had gotten tired of being told by AM stations that his signal was terribly distorted, and figured that a CW op would at least have his BFO switched on. This QSO couldn't have taken place if the Canadians weren't allowed to operate down into our CW bands.

Now I return you to the CW/SSB flame wars. Have fun.

OldBiker,
Just as a point of information, the old saying, "CW gets
through where voice doesn't", is a carry-over from the 'AM'
days, when it was true. If your using SSB, the saying is
no longer true (given the same circumstances).
'Doc

Computer based CW programs are easily defeated. Mostly,
because they are 'digital' in nature. Why not use an 'analog'
based computer which doesn't have the same constraints? While
the 'fist' still needs to at least be 'close' to 'good', it
doesn't have to be as 'close' to 'perfect' as required by a
digital program. The 'best' analog CW decoding device is
organic in nature and is normally located between a person's
ears (I've also heard some that seemed to be located in another
place).

Last I checked, there was a wide variety of formulations and materials available, and I'd hesitate to accept any "typical" values.

A Google web search of "EMI coatings" gave about 80 hits, mostly coating manufacturers. Any of these should be able to furnish detailed information about their products, and you'll probably find quite a bit on their web pages.

If you're interested in absorptive coatings, see Emerson & Cuming's offerings at http://www.eccosorb.com.

StarGazer,
All privileges of amateur licenses are not created equal.
Countries have different requirements and priviledges in their
licensing structure. All countries can't (and shouldn't) be
like the U.S.A., different strokes for different folks, you
know?
If you don't like the way the licensing structure works in
the U.S., petition the FCC to change it. You'll need some very
good reasons, and because "they" can, isn't a very good reason.
It becomes more understandable if you know the history of radio
in this country, at least you'll understand how some of the
rules came about. It also gives you a better knowledge base,
which really comes in handy when you want to change things.

hey there
a 1/4 wave on 6 is 54 inches its rather tough to get something that long on an HT
something that long will cause undue stress on the antenna connection
the best thing you can do is put up an outside antenna and use an adapter to
connect the coax to it

CW has a considerable edge over SSB as far as signal/noise/bandwidth
goes. What I objected to was: "CW gets through when no other mode will."
That means CW will get through on 10m at night during the bottom
of the sunspot cycle. It ain't gonna happen.

When feeding a ground mounted vertical with coax what is the standard method of routing the feedline to the shack? I would think you would have to bury it or be very careful when you mow the lawn. If you do have to bury it does it have to be in conduit or PVC? Could be they make some super coax these days that can be buried without the need for conduit. Seems like conduit could fill up with moisture if you are not careful.

The problem that I have is that I live in a house with aluminum siding, a patio with tin roofing, a neighbor on one side that has already tried to sue us over a tree and fence on the property line and tried to include my dipole antenna in the suit (he said it was a very dangerous wire hanging above their heads) and I can only get up about 25 feet from poles I have mounted at two corners of the back yard. I don't care if I take out every non-FCC compliant appliance the one neighbor has, but the other neighbors are pretty decent so I try to minimize the amount of wire I have running back and forth in the yard and over our house.

That's why the Isotron, if it worked even half decent, would be a good alternative. I don't chase DX, I don't get into contests, I'm not into nets. I'm just your basic, old fashion ragchewer that has a group of people (including my dad) within Oregon and the neighboring states that I would like to be able to talk to on 160. But I've used enough marginal antennas to know t hat if the Isotron was as good as they would have you believe that a lot of people would have them. I just don't know how many people do, so that is why I asked on here. So far I seem to be getting a pretty good idea of how well it works. <grin>

Right now I have a 80 meter dipole (it's actually an 80/40 something that has been around for a long time and I can tune on most of the other bands as well) that is about 105 feet total length (it's been up awhile and I can't remember what I measured it as). It is in the shape of an L (with the two legs almost equal), with one leg down the length of a 75' 6 foot wood fence and up about 22' on a telescoping mast that is bolted to a post near the end of the fence.

The middle with the 259 connector is up about 25' on another telescoping mast. The other leg goes up about 30' into a tree that is straight out in the front yard (and is also the tree the neighbor tried to sue us to get cut down). The tree is about 60' high and is a big Siberian Elm. I've tried to get a line over some of the higher limbs, but I've not had any luck. I can't use an arrow because of the houses around and I've been hesitant to use my slingshot for the same reason. The two angles I need are either towards the grouchy neighbor or into our house.

I've tried bringing another leg back over the house, but it's a two story and the wire was only a couple of feet over the roof and right over my wife's office who is on the phone a lot. I don't know why, but she doesn't like being on the receiving end of my ham conversations. <grin>

I should be glad that I can talk on 75 to 10 meter bands with what I got. A lot of people can't even do that with the limitations they have. One of these days we hope to move to someplace that has some land with it, maybe then I'll be able to put up a full size 160 meter dipole.

Thanks

Mike

Hi William,

As I said in my previous post, I don't chase DX. I did use a mag mount loaded 75 meter antenna on top of a trailer I was living in for awhile. If the Isotron worked as good as that I'd be satisfied. But I doubt it will. with the 75 meter antenna, even though it had a very narrow bandwidth, from Central Oregon I was able to talk to most of Oregon, Washington, Idaho and Calf. That was from the valley that I was staying in. Of course when the bands were marginal I could barely get out of the trailer park, but I've had that happen with the best of antennas.

Well, at least I asked before buying one and trying it. I'm just going to have to be satisfied with 75 to 10 until I can get some space around me to be able to put up something for 160.

Thanks for the comments.

Mike

Hi,Levent
you wrote
> Lets say I am using #14 ST. type cable from Home Depo and I am trying
> to feed this system with a coax (52 ohm) what is the best balun 1:1 or 1:256
> (Joke).
So the unbalanced port of the balun goes via the coax into the rig -
O.K. One pin of the balun's balanced port goes into the wire - still
clear. And the second pin of the balun's balanced port goes where ? To
nowhere ? Is it an open circuit with (almost) infinite impedance ? But
transforming infinite impedance in 1:anything ratio results still into
infinite impedance ! NO, NOT THIS WAY.
A commonly sensed longwire antenna is a piece of wire more than two
wavelengths long on the lowest working frequency (the length is
usually non_integer_number * half_of_wawelength on ANY of the working
frequencies to avoid very high impedances) connected DIRECTLY to the
center conductor of the rig's antenna connector. The rig's case,
grounding, power outlet etc. form together the other half of the
circuit, though rather unpredictable.
If you are looking for something more predictable, search the web for
end-fed wire antennas, e.g. the Zeppelin or bazooka antenna.

the most creative solution to restrictive covenants that I have seen
recently is
to buy an old pick-up truck, mount the biggest mobile antenna you can find
on it, park it outside your house and run a feeder into the shack - bet your
covenants don't mention car aerials!

Better yet, buy an old, barely running, severely beat up,
UPS van. Then buy and place on top of the UPS van a rooftop
tower with assorted antennas, rotator and verticals.

When you are home you can run a power line out to the truck
to "charge the battery" (wink). In fact, you could build the
whole station in the van and have room to spare.

Just think of the new friends you would make in the
community and no bitching from the YL because you junked up
the house with your radio gear. <G>

1131. Folded dipole wound around tower

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-17 12:51:17 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <yNz18.41$eh3.34287@newsfeed.slurp.net>
Source record: 150619

Hope not to start another waving-dead-chicken-and-mumbling-incantations thread.

Anyone out there remember the 80M f-d wound around two plastic hula hoops?

It sorta-worked.

Helically space-winding the same f-d vertically around one of my former R25 towers, worked, in the early seventies, in the anec-data sense: it heard and talked DX about as well as anything else I ever rigged in a 50-ft-wide urban back yard.

Is it worth expending some energy and time on such a project in this day and age? I have a lot more room now, but these tantalizing old ideas waft in over the transom from time to time ;o)))

Would modelling the thing at a frequency high enough to get around segment-limitations have any validity?

What effects could the tower 'core' have on the thing?

'Preciate all pertinent thoughts, and remember, I do not want to start another waving-dead-chicken-and-mumbling-incantations thread.

1138. Re: MW Folded Unipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-17 17:31:02 UTC
From: sjbeyers@trianglenet.net
Message-ID: <72befaab.0201170931.5c11cb5b@posting.google.com>
Source record: 150626

I've been using a short vertical (42 feet) on 160 meters, and it works fine at 100 watts. But when I try to go to higher power (500W or so), unpleasant things start to happen. I've been wondering if running a wire up the side of the antenna (it's a steel tower), connecting it at the top, and feeding at the bottom as a folded monopole, would increase radiation resistance. This (I hope) would make for lower swr and the ability to run more power. I do all matching in the shack with a "balanced-L type tuner, and use tis antenna on all bands. I can, and do, on occasion, run 500+ watts on all other bands (except 30M, of course).

I've been playing with modelling this with EZNEC. The results seem to be what I would expect with antenna heights in the neighborhood of resonance. But with very short folded monopoles (42 ft, like mine), the results vary widely with different conductor diameters and different nubers of segments used. After trying a variety of combinations, I think maybe I could increase radiation resistance from about 2 ohms, which it is with my present monopose, to about 11 ohms with a folded monopole. Does this seem reasonable? Am I making mistakes (as usual) in modelling or reasoning?

Ordinarily I would just go ahead and try something like this, but it's cold outside, so I thought I'd ask first. Thanks.

1139. Re: LONG WIRE Antenna feed point Z?

Thanks for the info Ivan but I do not agree with you. If you look ARRL Antenna Handbook or the ARRL WEB page you will see that harmonic antennas can be feed only at the end or at a current loop. But current loop fed is not considered as a real LONG WIRE feed because of the single frequency behavior of the current loop (Antenna Hand Book page 13-3) Look Baker & Williamsons Vee antenna http://www.bwantennas.com/eng/veeant.eng.htm it does feed at the end. Look the Beverage Antenna http://www.geocities.com/CapeCanaveral/1138/bev-page.html it feed at the end and has 1 wl or 2 wl size and years used for transmission also (1940s). I do NOT think this antenna has Infinite impedance on one end !

Check the line voltage with a multimeter. That will tell
you if it is
a load problem or not. I once had a problem similar to
yours, and it was
because the screws connecting the AC line in the breaker box
were loose.
Tightening them down cured the problem.I thought it was RF!

Doc,

Are you refering to a tower wound antenna for 80/40m or the second question I had on cross field antennas?.

If it is the one about cross field antennas, then I saw some interesting photos on the following site that claims to have had good results on HF. See what you think,

http://www.qsl.net/master.htm

Then select W0KPH.

Its very roughly in the direction broadside on; that is to the East or West.
Better deal is to move until you get the least signal. One end of the
antenna bar is then pointing at the station. This may be inaccurate at night
on distant stations. mountains will have little effect by day.

1145. smartuner repair

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-17 23:02:08 UTC
From: Snafu <snafu@starband.net>
Message-ID: <aKI18.23$xR.4548726@twister1.starband.net>
Source record: 150632

I have a SGC model SG-230 Smartuner that I bought about six years ago for a mobile application. I didn't work out (back then) and I stored it under cover in my garage until now. It never was exposed to any weather.

Recently I put up a long wire and thought I would finally use this expensive peice of equipment that I have been storing all this time.

As luck would have it, I can not get it to tune. I know it has power to it but it will not even attempt to tune on any band. It "clicks" on and off when 12v dc power is applied but I do not hear the tell-tale "chattering" of the relays when Rf power is applied. (and the VSWR is on the moon on every band) I do have a couple ground rods and I believe the antenna is properly grounded.

I called SGC and they would be happy to make it work for the sum of $265.00! It's a flat fee they charge regardless of what is wrong!
Does anyone have any ideas about how I can get this working for a lot less than that? I can use a meter and a soldering iron, but that is about where it ends.

Actually it does quite a bit. Just people don't notice it much. Sporadic E and sometimes the fluke nighttime F layer stuff can crop up at the weirdest times. Of course, being many people are asleep, many miss it. I remember a few years back a few locals did a 17m propagation "study" where they got on 17m at about 1-2 AM every weekend for quite a few months. I used to get on and help them listen sometimes. You'd be amazed at what you can work when the band is "dead". We found if you get out there and make a lot of noise, you will dig up qso's. Even in the middle of the night. We worked all over the world. Many times with booming signals. But at a casual listen you would think the band was dead. :) BTW, we worked ssb, so not related to the cw argument. I think cw is still about the best for weak signal work. Just as good as psk31, etc, etc after trying those modes. I think PSK31 is over rated in the s/n area. I notice if I start to lose audio reception , I start to lose print also. I seem to have to hear the psk to some degree to decode it. About the same as CW, so myself, I consider them about equal really. Note that on 70 cycle longwave they like to use real super slow cw that is detected with puter programs visually. MK

LOL! But then you'll have the ones who *may* point out an ordinance against
dilapidated,
non-running vehicles in the yard. Many cities have these ordinances that
have nothing to do
with CC & Rs, and there are plenty of grumpy, busy-body neighbors that would
take advan-
tage of that!

The best solution is to find an older neighborhood that has no covenants and
blue-haired old
ladies telling you what you can and can't do on your own damned property.
That's what I
did!

I use rg-213. It's an RG-8 equal that has a direct burial jacket. Also
mil-spec shield. The specs are about the same as rg-8 as far as
losses,power handling , etc. Half my coax is 2 inches deep in water
when it rains hard and the water is gushing off the roof. I just have
it laying on the ground. I don't bury it. But I could though if I
wanted to. MK

1149. Re: MW Folded Unipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-17 23:30:21 UTC

Source record: 150635

Folding the antenna will multiply the radiation resistance -- as seen at the feedpoint -- by a factor of four. It'll also multiply the reactance by four, and the loss resistance as seen at the feedpoint by the same factor. So it won't do anything to improve the efficiency. You might or might not find it easier to match the new feedpoint impedance with four times larger resistance and reactance.

Snafu,
Do you happen to have the service manual, or at least a
schematic for the tuner? If you do, and if you're not
comfortable
trouble shooting it, take it to a reputable shop ~with~ the
manual or schematic. They're much more apt to 'take a look' at
it with those. If you don't have them, well, it still doesn't
hurt to ask...

==========
Only if the pair of conductors have the same diameters. Unequal diameters
result in different transformation factors.

Source record: 150640

You're absolutely correct. And when the diameters are different, it also depends on the wire spacing. The transformation factor can be a lot different than 4 if the diameters are very different. Another thing to keep in mind is that by folding, you've created a shorted transmission line stub across the feedpoint. When the monopole is nearly a quarter wave long, the impedance of this stub is high and can often be ignored. In shorter monopoles it should be considered.

But the ground loss is always transformed by the same factor as the radiation resistance, and the ground loss is always the same before and after folding.

Thanks for the correction. I apologize for the oversimplification.

1155. Re: ISOTRON 160 meter Antenna? How well does it work?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 03:14:11 UTC
From: whagen6@cs.com
Message-ID: <20020117221411.15641.00005117@mb-ci.news.cs.com>
Source record: 150642

If you have an 80 meter dipole, you have the basics for an antenna that will surpass the isotron already. take a short piece of coax with connectors on both ends, and cut it in the middle, cut the shield all around, and short it to the center connector. Insert this in between your coax and tuner, with the end with the shield floating on the tuner side. You have just converted you dipole into a tee for 160, worked against ground. A good set of radials helps. Just match it with the tuner. I will be not as efficient as a dipole but better than nothing...
It works well for a compromise antenna, give it a try.
You can also cut the connector off and connect the center wire to the longwire terminals of your tuner if it has them etc.

1156. Re: ISOTRON 160 meter Antenna? How well does it work?

Source record: 150643

see my posting on the other thread, about making a tee from your dipole.
I have done fairly will with the isotron, from chico into oregon and
washington, also with the tee configuration. Currently I have a 120 foot wire
that is in an inverted vee config, fed at the end, and the center is about 45
feet up. the other end goes to the back fence, stand off a few feet with and
insulator. I worked new jersy from chico the other evening, and have workd
mexico city on it, 160 meter band.
If you want to spend the money, get a screwdriver antenna, do the 160 meter
mods to it. It works well too, the key is the base of the screwdriver has high
current, thus good radiation.

Here's a shot in the dark for you. My SGC-230 quit working and the problem
was that the internal connection on the output post had loosened. I took the
cover off, discovered the loose connection, and tightened it up. Worked
like a charm after that.

1159. Anyone have experiance of 6mtr tonna.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 04:46:22 UTC
From: chris <chris.c@ntlworld.com>
Message-ID: <1NN18.43594$_x4.6481208@news2-win.server.ntlworld.com>
Source record: 150646

Has anyone on here had any experiance or problems with the tonna 5 element 6 mtr yagi....??

I seem to be have loads of probs.......

I put it together as per the instructions and put it on 30 feet of pole, but the SWR is high...i tried re-doing the conections, but its no better....the SWR is supposed to be good between 49.5 Mhz and 50.5 Mhz, but mine is 6:1 from 50.0-50.56 Mhz and then drops slowly across the next 150 Khz down to 1.1 back up to 6:1.

I now have the aerial 4 feet off the ground in the garden and the SWR now is 3:1 from 50-50.5 Mhz and then goes up after that.

Is there some sort of mod for this aerial that makes it work, or have i got a bad one that needs putting in the bin.

Any help please.........Cheers...Chris.

1160. Re: What is 6ALJ Antenna?

Newsgroup: rec.radio.amateur.antenna

From: marcabsolutelynospam@laradio.spamfree.co.za
Message-ID: <3c47c702.2240123@news.megaweb.co.za>
Source record: 150648

The 6ALJ is a broadband dipole type antenna manufactured by Webb Industries in Johannesburg, South Africa. It went out of production about five years ago. According to Terry Reuss, the R&D Engineer at Webb, the royalties on the design were too high, so production was stopped. I don't know who the designer or original manufacturer was.

The antenna itsself if a folded dipole type, made from incredibly durable materials. The main target market was the South African military and the Police. It was a very expensive antenna in it's day (around $1700-00), and it could handle around 5kW.

A pretty inefficient antenna, but if you put enough power into it, you would get reasonable results. If memory serves me correctly, it is a 4 to 30 MHz antenna.

I have one and the loose output post happened to me. Also the relays would only pull in and begin to work at 13.0 volts after a couple of years, you might check the volts to the unit.

Otherwise, I have used it all over the world and it works like a champ.

Probaly RF to the mains wiring, or if it goes dim when you key, you have
very poor regulation on the incoming power line to the shack.

Hi Levent,
as can be seen on the picture at
http://www.bwantennas.com/eng/veeant.eng.htm
, one pin of the symmetrical side of the balun connects to the wire of
the vee antenna and the other TO THE GROUND. Similarly, looking at a
Beverage antenna schematic (e.g. http://www.qsl.net/aa3px/design.html
), one end of the high impedance winding of the transformer connects
to the wire, the other TO THE GROUND. (The low impedance winding
connects to the coax of course.) In none case it leads "to nowhere".
Yes, the wire itself is end-fed, but the ground is an active part of
such antenna systems, has a finite impedance and completes the
circuit. The same is valid for many other types of antennas, as simple
verticals (whips).

Finding a neighborhood amenable to hobbies IS the way to go...Even if the residents try to create an association, they can't unless they have 100% cooperation throughout the neighborhood. In my neighborhood some of the guys tried to trick us by collecting funds for a beautification project. "Make your check out to suchandsuch association." I told them I'd donate green stamps but they balked. I guess they figured if they could get me to write a check recognizing a new homeowners' association that they'd be able to formalize something.... Be aware.

Alan

1166. FS: SMA-to-BNC custom fit antenna adapters

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 14:03:13 UTC
From: gulyas@earthlink.net
Message-ID: <12235960.0201180603.593eddcb@posting.google.com>
Source record: 150654
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.swap,rec.radio.scanner

If you have a need for a high-quality SMA-to-BNC antenna adapter that is
custom made to fit and protect your H.T. or scanner radio, I have the part.

Adapter allows you to:
Quickly change antennas to base,mobile or different style use.
Use the more popular and wider selection available of BNC antennas.
Prevent chassis connector wear or from coming loose due to antenna
changes.

Adapter features:
Gold plated contacts with a teflon insulator.
A low profile design with a rubber covering for a factory antenna look.
The rubber base seals to the top of the radio with no spacers needed
for moisture and dirt protection.
The base also provides an excellent support for any length of antenna
or application.
No need to remove adapter once installed to make a quick and safe
antenna change.

Sizes to fit radio models:
Yaesu: VX-5, VX-1, FT-50-R, VX-10, VX-150, VX-110, VXA-100, VXA-120
Icom: IC-T8A, IC-T81A, IC-Q7A, IC-R2
Kenwood: TH-D7, TH-G71, TH-F6A
Alinco: DJ-V5
Standard: C508A, C510A
Radio Shack: HTX-200, HTX-400, HTX-245
Aor: AR-16

Previewed in the May 2000 Issue of CQ Magazine, and the Nov. 2000
Issue of QST Magazine.

$11.95 + $1.50 S+H(One to unlimited)
(Check or money order only in U.S.Funds)
(Specify-radio-model)

Roy Lewallen, W7EL wrote:
"Folding the antenna will multiply the radiation resistance ---as seen at ther feedpoint--- by a factor of four. It`ll also multiply the reactance by four, and the loss resistance as seen at the feedpoint by the same factor. So it won`t do anything to improve efficiency."

I think efficiency improves.

ON4UN in "Low Band DXing" Table 9-2 gives earth resistance from 28.6 ohms for two radials which are too short, to 0.1 ohm for 120 radials which are 0.4 wavelength.

Let`s go for the middle and pick 14 ohms for our ground resistance.

Arnold Bailey in "TV and Other Receiving Antennas" gives 28 ohms as the drive impedance of a perfect 1/4-wave vertical antenna (no ground loss). Bailey gives 150 ohms for a folded unipole (no surprise).

Imagine an equivalent circuit. Our transmitter is connected between a vertical antenna and the earth. There is a complete circuit though it may appear open with what we`ve drawn so far. There is a capacitance between the antenna and earth but it`s not shown in diagrams.

All the antenna current produced by our transmitter flows through our antenna, through the space surrounding our antenna, then through the earth back to our transmitter.

For our purposes, we can redraw our equivalent circuit. Lets replace the antenna with its drivepoint impedance. Replace the space between the antenna and earth with a wire. The capacitance is high enough and the wire like the space has no loss. Replace the earth with a 14-ohm resistor, from the middle of ON4UN`s table.

Now, our equivalent circuit is simply a transmitter with two resistors in series across its output. One resistor is either 28 ohms for the whip or 150 ohms for the folded unipole. The second resistor is the earth resistance which we picked as 14 ohms for our example. We can`t change the earth`s resistance by adding a wire to the vertical antenna.

Let`s pick 100 watts as the power fed to our two resistors in series. In the first case we have 28 ohms in series with 14 ohms. The power divides as the resistances, so by inspection we have 67 watts in the antenna and 33 watts lost in the ground.

You can work it out. You have 100 watts in 42 ohms. E=sq rt PR. E = 65 volts, I =1.54 amps, P=IIR=67 watts in the antenna and 33 watts in the earth loss.

In the case of the folded unipole, you have 100 watts in 164 ohms. E=128 volts, I=0.78 amps.
P=91 watts in the antenna and 9 watts in the earth loss.

I`ll take the efficiency of the folded unipole.

Best regards, Richard Harrison, KB5WZI

I wrote:
"I think efficiency improves."

Wrong!

Phil, G4ZOW attached a report presented to the NAB by du Treil, Lundin, & Rackley of tests comparing base insulated antennas with similar folded unipoles. There was no difference in signal strengths.

Their conclusion was that no difference in displacement current exists if the power radiated is the same. So current in the ground is the same for either type of antenna. Same current, same loss.

Their tests prove the case.

My mistake was using drive point impedances. The radiation resistance must be the same for both antennas if radiation and ground loss are the same for both antennas.

Best regards, Richard Harrison, KB5WZI

1176. Copper J Pole in tree for 2M

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 18:34:04 UTC
From: "Andrew C. Ohnstad" <spam.sux@die.spammers.com>
Message-ID: <MPG.16b234a580f69cbf989699@news.rcn.com>
Source record: 150665

Hello all.

I am building a "copper cactus" J-Pole for 2 meter use. My mounting options are limited to a number of very tall trees in my back yard. My plan is to use a slingshot or something to get a piece of rope or strong fishing line over a high branch. Then I'd like to tie the J-Pole to the line and hoist it up, dangling it from the tree branch.

What I don't know is if I can drill holes in the antenna to tie off the line to. My options are to drill a small hole in both the 1/2 and 1/4 wave sections at the top, or drill one hole in the bottom part (which is commonly shown mounted to a mast) and hanging the thing "upside down." I'm going to try my hand at some basic ascii art here...

```
|<----------add hole here
|
| |<-------add hole here
| |
|--|
|
|
```

OR hang it upside down in the tree like so...

```
|<--------add hole here
|
|--|
| |
| |
|
|
```

This is my first homebrew antenna project and I really don't want to screw it up! Thanks!

AMATEUR RADIO NEWSLINE(tm) REPORT #1275 - January 18 2002

Amateur Radio Newsline report number 1275 with a release date of
Friday, January 18th 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T. A new ham antenna on the I-S-S and a new microwave record down-under are first on Amateur Radio Newsline report number 1275 coming your way right now!

(Billboard Cart Here)

**

HAM RADIO IN SPACE: NEW ANTENNAS INSTALLED ON THE ISS

An American astronaut and a Russian cosmonaut ventured into space on Monday January 14th to move a construction crane and install a new set of ham radio antennas on the International Space Station. Roy Neal, K6DUE, has the details.

--

THERE IT WAS, ON NASA TELEVISION, TWO WHITE SPACE SUITED CHARACTERS, DWARFED BY THE IMMENSITY OF THE INTERNATIONAL SPACE STATION. FOR THE 32ND TIME ASTRONAUTS AND COSMONAUTS WERE OUTSIDE THE HUGE SPACECRAFT TO ASSEMBLE HARDWARE.

THEIR PRIMARY OBJECTIVE WAS TO MOVE A BIG CARGO CRANE FROM ITS TEMPORARY BERTH ON THE UNITED STATES SIDE OF THE ORBITING OUTPOST TO A PERMANENT LOCATION OUTSIDE THE DOCKING COMPARTMENT OF THE RUSSIAN CONTROL MODULE.

THAT ACCOMPLISHED, THEY WENT ON TO UNFURL A HAM RADIO ANTENNA. ASTRONAUT CARL WALTZ, KC5TIE AND COSMONAUT YURI ONUFRIENKO, RK3DUO, DEPLOYED THE RIBBON OF TAPE THAT SOON WILL BE IN USE ON A HAM RADIO STATION IN THE SERVICE MODULE,. WHERE THE CREWS LIVE AND SLEEP. A SECOND STATION HAS BEEN IN SERVICE FOR SOME TIME INSIDE THE SO CALLED FUNCTIONAL CARGO BLOCK, ANOTHER SECTION OF THE I S S.

FRANK BAUER, KA3HDO, THE CHAIRMAN OF ARISS, THE GROUP THAT IS RESPONSIBLE FOR AMATEUR RADIO ON THE SPACE STATION, CONGRATULATED THE INTERNATIONAL TEAM OF LICENSED HAMS FOR THE SUCCESSFUL CONCLUSION TO MONTHS OF HARD WORK.

ON JANUARY 25th ONUFRIENKO IS SCHEDULED TO GO OUTSIDE AGAIN, WITH FLIGHT ENGINEER DAN BURSCH, KD5PNU, TO INSTALL 3 MORE HAM RADIO ANTENNAS OUTSIDE THE MODULE THEY CALL ZVEZDA, THE CREW COMPARTMENT THAT'S THE SIZE OF A PASSENGER BUS HERE ON EARTH.

HAM RADIO IS GROWING RAPIDLY IN SPACE, ALONG WITH THE INTERNATIONAL STATION ON WHICH IT'S INSTALLED.

FOR THE AMATEUR RADIO NEWSLINE, ROY NEAL, K6DUE

--

The Expedition 4 crew will remain on board the ISS until May. And according to Frank Bauer, KA3HDO, another important task is to bring the automatic packet system back on line. He says that ground technicians are working with the astronauts and cosmonaut on that project and that task will continue as crew time permits. (ARNewsline from information provided by ARISS, NASA.)

**

HAM RADIO RECORDS: 24 GHZ DOWN-UNDER

A new distance record is set on a band where even commercial interests are only now starting to tread. And its a group of Australian hams who have set it. Q-News Graham Kemp, VK4BB, has the details:

--

A new Queensland distance record on 24.048.1 GHz USB was established morning of Tuesday 08 January over a 72.8 Km path. Location 1 was at Wellington Point, with VK3ZQB and VK4ZHL portable. Location 2 was at Caloundra, with VK3XPD and VK5DK portable operating.

Signals strengths up to 5x5 after initial optimization with typical daytime QSB. The visiting team are continuing with local propagation experiments. The challenges of building and operating microwave amateur radio equipment are wonderfully rewarding in many ways!

From Q-News Australia, I’m Graham Kemp, VK4BB, for the Amateur Radio Newsline.

--

Further experimentation is expected to bring even more record setting contacts in this very microwave ham radio band. (Q-News)

**

RESTRUCTURING: BIG LICENSING SUCCESS IN THE UK

A new slow-code license recently introduced in the United Kingdom is also setting records. This in the area of people flocking to get it. Jeramy Boot, G4NJH, days that the new British Foundation License is on its way to becoming a major success:

--

The Radio Licensing Center reports that, as of the 7th of January, exactly 600 of the new M3 Foundation Licenses had been issued.

In the 'QSO Party' for Foundation Licensees that took place on the 1st of January it is estimated that about 100 M3 stations were active. Many joined the one-minute-past-midnight 80-meter net and many more were heard working DX during the subsequent days.

One person active on the 1st of January was Mike Marsden, M3BQH, who also holds the callsign G8BQH. Mike reports that he worked Alex, UR5EDU, in the Ukraine at

two seconds past midnight, using 10 watts on 40 meters. The report was 59+10dB. After a few hours' sleep M3BQH worked 66 stations on the first day, with only two short CQ calls.

"The pile-up queue was never ending, I even managed to work seven other M3s", Mike said.

Jeramy Boot, G4NJH

--

To put this in perspective. The UK has 57,814 hams so 600 is about 1%. Here in the United States we have close to 625,000 licensees. That’s the equivalent of getting 6250 hams signing up for a new license class here in the USA in only a few short days. (GB2RS)

**

BREAK 1

This is ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, including the W8GK repeater serving Charleston West Virginia.

(5 Sec Pause Here)

**

RADIO REGULATIONS: FCC'S APPROVES DRAFT WRC PROPOSALS

The FCC’s Advisory Committee for the year 2003 World Radiocommunications Conference has approved its preliminary draft proposals. The document has been assigned as D-A-02-101 and deals mainly with satellite and terrestrial allocations in the UHF and microwave bands. Amateur Radio is only briefly mentioned in the area of 890 to 1350 MHz allocations.

The Advisory Committee itself was formed in January of 2001 to assist in the development of United States proposals for WRC 2003. DA-02-101 is based primarily on the committee report. Comments on it are due on it no later than January 28th.

The complete of 55 page text of DA-02-101 is on the FCC website at http://hraunfoss.fcc.gov/edocs_public/attachmatch/DA-02-101A1.txt (FCC)

**

ENFORCEMENT: CLEAN UP THE INTERFERENCE - PLEASE

The FCC has written to an A-M radio station and an electric power provider to help resolve an unusual and long-standing interference situation. One affecting local amateurs in the Cincinnati and Mason Ohio areas. Amateur Radio Newsline’s Don Wilbanks, KC5MFA, brings us up to date:

--

The letter suggests that multiple sources may be involved in this interference case. Also that two that are possibilities are Cinergy Corporation and radio station WLW. Cinergy is the electric company to the affected area and WLW is a Clear Channel Communications owned power-house AM station serving the greater Cincinnati area from a transmitter in Mason.

WLW operates on 700 kHz with 50,000 Watts into a single element diamond shaped half-wave vertical tower. This is only one of two such towers left in the United States, the other belonging to WSM AM in Nashville Tennessee. Both were constructed in the early 1930's by the now defunct Blaw Knox Construction Corporation.

One of the amateurs affected is Bob Reiff, WA8ULW, of Mason. Reiff told the ARRL Letter that while the noise is most noticeable on 160 meters, it's showing up elsewhere. He says that some local hams suspect it is even causing problems even on a two meter repeater.

In its letters, the Commission says that it recognizes this to be an unusual case. It says that the source of the interference could turn out to be something else unexpected. But the Commission adds that it is turning to the radio station and electric utility company and asking for their help in finding the source of the noise plaguing the Mason ham community. It's also asking that both cooperate with the technical experts from the American Radio Relay League in solving the problem.

For the Amateur Radio Newsline, I'm Don Wilbanks, KC5MFA.

--

By the way, More information on this very interesting Blaw Knox diamond tower design and the ones installed at both WLW and WSM is available on-line. Simply take your browser to http://www.wsmonline.com/w_homepage/tower/index.html. Its very interesting reading. (FCC, ARRL, Amateur News Weekly)

**

ENFORCEMENT: UNLICENSED OPERATOR TOLD TO EXPLAIN

A former ham that the FCC says may have been on the air without a license has been asked by the agency to provide an explanation. The person posing the questions is FCC chief ham radio rules enforcer Riley Hollingsworth, K4ZDH. And in a recent Rain Enforcement log, Hollingsworth outlined the situation:

--
Hollingsworth: "We requested clarifying information from Brian Bailey, ex-KD5PXQ. His license was set aside by the Wireless Bureau on October 19th. We want to know his exact whereabouts on two specific days in September. Bailey has been in touch with us and is deciding weather to provide the information."
--

According to Hollingsworth, the information that the FCC wants from Bailey relates to allegations of unlicensed operations and malicious interference. (FCC, RAIN)

**

HELPING HAMS: HAMDIHAMS NEW E-MAIL ADDRESS

This note: The Courage HandiHam System has a new electronic mail address. You can now reach the group at handiham@courage.org. You may also contact its Director Pat Tice directly at wa0tda@arrl.net. (HandiHams)

**

CONVENTIONS: HAMVENTION SAYS BRING YOUR BUS AND LAVE THE PARKING SPOT TO US

Free parking at the HARA Arena for Hamvention? Well, kind of. Its free if you leave your car at home and charter a bus to bring in a pretty large group of people to the event. Amateur News Weekly's Phil Thomas, W8RMJ has the not so complex details:

--

For Amateurs who charter a bust to make the annual journey to Hamvention, the Dayton Hamvention Committee will reserve a parking place for your chartered bus for the entire three days of Hamvention. The reserved parking will be close to the HARA Arena Complex, allowing not only a place to secure your valued purchases, but also a place to rest those weary feet after walking many, many miles of Hamvention. Space is limited for the new charter bus parking area. Pre registration is required. Availability is on a first come, first served basis.

--

For more information on the new on-site charter bus parking offer or to reserve a space, please contact the Dayton Hamvention office. It's open normal business hours Eastern Standard Time at are code (937) 276-6930. You can also fax your request toll free at
1-800-491-4267. (Amateur News Weekly)

**

CONFERENCES: SE VHF SOCIETY IN APRIL

Greg Robinson KB4NVD says over the VHF Reflector that the Sixth Annual Southeastern VHF Society Conference will take place April 26th through the 27 Th. in Oak Ridge, Tennessee. The conference, hosted by the Southeastern VHF Society, promises to be an interesting and exciting event with presentations from accomplished VHF and up amateur radio enthusiasts from several parts of the country. Registration, program details, hotel and travel information can be found in cyberspace at www.svhfs.org. (SE VHF Society)

**

HAM RADIO EVENTS: KIDS DAY A BIG MID-WEST SUCCESS

The first Kids Day operating event for 2002 was a rousing success in many venues. But in one Mid-West city a bit of coverage on a local T-V station helped to make it even better. Again to Amateur News Weekly and reporter Jack Parker, W8ISH:

--

Kids Day at the Indianapolis Chapter of the American Red Cross got a boost when event coordinator Stece Wendt, KB9RDS, made an appearance on a local TV news program. During the two minute segment. Wendt told viewers that all kids and their parents were welcome to share in the Amateur Radio experience, including an introduction to Morse Code, VHF repeaters and HF:

--
Wendt: “And then we turn around tand take them over to the big radios -- the big base station radios where they can talk -- literally -- around the world.”
--

This is the second year the local Red Cross chapter has shown young people how to tune in the world.

Reporting from Indianapolis Indians for Amateur News Weekly, This is Jack Parker, W8ISH.

--

This is just one of many Kids Day success stories. We will have more in future Amateur Radio Newsline reports. (Amateur News Weekly)

ARNEWSLINE(tm) FINANCIAL UPDATE WITH N6TCQ

It’s time for a report on the financial situation here at Amateur Radio Newsline. With it is our Support Fund Administrator and Corporate Treasurer, Andy Jarema, N6TCQ:

--

It is January of 2002. A brand new year for ham radio. And the beginning of another year for us here at the Amateur Radio Newsline. And as we start off the new year, here are the current finances.

Looking in the new corporate checkbook, the balance shows us at about $700 give or take a few bucks. Not very much when you consider that it takes over a thousand dollars a month to produce these weekly 20 minute Q-S-T’s.

Obviously, Amateur Radio Newsline is going to need your help -- and -- need it quickly to keep it from going away and to keep the news of ham radio coming your way.

We have done all that is possible from our side to keep costs under control. But, some fixed expenses like the telephone and long distance calling are a must have. So are electronic mail and world wide web access. There is the cost of the routine maintenance on the tape machines and editing gear. And in a few months the Newsline sponsored Young Ham of the Year Award will be rolling our way. All of this adds up and some costs just keep going up. When you add it all up and average it out, it comes to that $1000 a month figure I just mentioned.

So now is the time when Amateur Radio Newsline has to ask to ask that you help to keep its newscasts coming your way. Your tax deductible contributions can be sent to the Newsline Support Fund, Post Office Box 660937, Arcadia California. The Zipcode is 91066.

Ill be back within the next few weeks with an update on how things are going. For now from the Amateur Radio Newsline support center, I'm Andy Jarema, N6-Tiny-California-Quake.

--

Don't worry if you missed the address. It will be repeated in a few minutes at the end of this weeks newscast. (ARNewsline(tm) Support Fund)

**

ARNEWSLINE(tm): WE ARE GOING MP3

One other piece of news concerning Amateur Radio Newsline. As of March 1st, we will be dropping Real Audio and going exclusively MP3. Why the change? Well ever since we began posting a downloadable MP3 file at our own FTP site along side the Real Audio file, 9 out of 10 people have chosen the MP3. And with good reason. MP3 simply sounds a lot better than Real Audio to most of you. And by dropping the Real Audio, we can make the MP3 sound even better by encoding at a higher bit rate.

Right now, you can still compare the two formats if you like. Until February 22nd we will continue to post both Real Audio and MP3. Take the time to download both. And don't worry. Most modern media players including Real Audio, Microsoft Media and Winamp play MP3 so the chances are that you are already equipped to cover of the digital format change. (ARNewsline(tm))

SCIENCE AND TECHNOLOGY: THE NOISE OF EARTH

According to Space Daily, researchers have known for three decades that the Earth is a potent radio transmitter, but they were never able to pinpoint where the noise was coming from. Recently, by using data from the four spacecraft of the European Space Agency's Cluster mission, NASA-funded scientists have precisely located the source of the radio noise along the magnetic field lines. The noise originates several thousand miles above bright regions in the Earth's
northern lights. (AMSAT, Space Daily)

INTERNATIONAL-CANADA: ARE AGREEMENT IN B.C.

Turning to international news, Radio Amateurs of Canada which sponsors that nation’s Amateur Radio Emergency Service has signed a Letter Of Understanding and the British Columbia Provincial Emergency Radio Communication Service. The letter represents the collaboration between Radio Amateurs of Canada’s British Columbia Section Manager Fred Orsetti VE7IO and Supervisor of Information and Communications Technology for the Provincial Emergency Program Andrew Bryan VE7KSN, to provide a cooperative plan to carry out emergency communication. The letter also further enhances the work of the Canadian ARES program and compliments the Memorandum of Understanding signed May of 1994 between Radio Amateurs of Canada and Red Cross. (RAC)

**

INTERNATIONAL - CANADA: VE1AWA RESIGNS AS MARITIME PROVENCES SM

Due to personal reason Roy MacIntosh, VE1AWA has stepped down from the position of Section Manager for the Maritimes. Tom Caithness, VE1GTC has been appointed acting Section Manager pending outcome of the upcoming election call. (RAC)

**

INTERNATIONAL - UK: AMSAT-UK COLLOQUIUM

The 17th AMSAT-UK Colloquium will be held at Surrey University in Guildford from the 26th to 28th of July this year. AMSAT-UK is now inviting speakers to submit papers about amateur radio space and associated activities for this event and for the Proceedings document. Offers of papers should be submitted as soon as possible and should be sent only to Richard Limebear, G3RWL. His e-mail goes to g3rwl@amsat.org. (AMSAT-UK)

**

HAM RADIO IN SPACE: WEBSITE UPDATE

AMSAT reports that IK8XLD has updated his website with information about satellite operations, EME, the ham radio operation on the International Space Station, ATV and homebrew equipment. You can visit Rocco’s website at www.qsl.net/ik8xld. (ANS)

**

DX

In DX, DJ4KW and DK9GG are active from Belize as V31YN and V31GW respectively until about the 2nd of February. Activity is on CW, RTTY and PSK 31. (GB2RS)

And KE1F will be active on 10 to 160 meters CW, SSB and perhaps RTTY as ZF2LM from Grand Cayman Island from the 14th to 30th of January. (GB2RS)

Also R1ANF began operations as CE9 slash R1ANF on the 29th of December from a Chilean base in the South Shetland Islands. He is active on 10 to 28 MHz with 100 watts to an R6000 vertical. For all three, QSL as directed on the air. (OPDX)

Last but by no means least, word that JX7DFA, is on a job assignment to Jan Mayen. He is operating as LA7DFA. QSL via his home call. He will reply when he returns home in the Spring. (Modern DX)

**

THAT FINAL ITEM: A CALL FOR ARDF HUNTERS FOR THE WORLD GAMES

And finally this week, 2002 may be the biggest year yet for fans of hidden transmitter hunts, especially the ones that are all on foot. Amateur Radio Newsline’s Joe Moell K0OV helps coordinate happenings like these and has news of two major events.
--

Every two years, hams from around the world gather to see who is best at on-foot hidden transmitter hunting, also called foxtailing, radio-orienteering and ARDF. There are separate events on eighty meters and two meters, each with five transmitters scattered in a forest that can encompass 1000 acres or more.

Competitors are divided into five categories for males and four categories for females. Each country may have up to three persons per category on its team.

Back in Y2K, the championships were in China, with a dozen stateside hams among the competitors from 26 countries. This year, the excitement moves to Slovakia and takes place from September 2 through 7. Once again, ARDF Team USA will be there.

Would you like to be on that team? If so, contact me right away, because USA must submit its Letter of Intent to the Slovakian hosts by the end of January.

Of course you'll need lots of practice beforehand, and you can get plenty by attending USA's own national ARDF championships, which will be April 19-21 in Pine Mountain, Georgia, near Atlanta.

Find out about both championships -- Slovakia and Pine Mountain -- by visiting my Web site: www.homingin.com. Homingin is one word. Then apply for the Team USA roster at my e-mail address on that site, or by postal mail to my callbook address.

Maybe you'll bring home a medal this year. From southern California, where this year's local radio-orienteering training sessions will begin soon, this is Joe Moell K-zero-Oscar-Victor for Amateur Radio Newsline.

--

In case you missed it, Joe’s website is www.homingin.com. “homeingin” is one word. (K0OV, ARNewsline(tm))

Not the Isotron. It's just an enlarged version of a tank circuit hung out in the open, at whatever height you can put it. Some of the versions in use on the higher bands do perform acceptably if minimally, but not on the lower bands. Down there the effiency has to be in the ~.001% area. (No, I haven't calculated it).
I picked up a 75meter version to use as a backup for local use. With it hung at 20 feet I was able to communicate 200 miles with it on 75 SSB in early morning when band noise and QRM was at a minimum, but with an (expected)very weak signal report. It truly was "just better than nothing".

1179. Re: Copper J Pole in tree for 2M

Newsgroup: rec.radio.amateur.antenna

Source record: 150668

hey andrew
well when you cap each end of the Jpole you can drill and insert the hanger into that
but if you try and hang that antenna inside the canopy of a tree the leafs on the tree will block the RF from your antenna and tou wont hear or be heard nearly as well as an antenna in the open
if you could climb the tree and attach a mast and the antenna on the mast so the antenna sticks out of the tree top would be a better idea
also remember that the longer your coaz run the more line loss you have and some of the coax generally used now adays have nearly 4db of loss at 150mhz at 100 feet
i assume the reason for the tree mount is you are deed restricted or a renter
there are a couple of antennas that can go on the roof and no one but you would know what they are one is called a ventenna and the other one is a weather vane if you would like i could give you the website for these antennas
good luck

Mike, several years ago, with winter close at hand and me wanting to use 160 during cold weather and with no 160 antenna for it up, I decided to put up an ALpha Delta DX-A Sloper, a shortened antenna of the approximate size, length and configuration of a 75 meter dipole, that works on 160, 75/80 and 40 meters. I figured it would be a minimal antenna but better than nothing. In short it turned out to work quite well, and I still have it in the air today as a backup, though a few years later I finally got a full size 160 meter dipole put up. It does require either a grounded metal mast of 30 or more feet, or an existing tower (which I have, 60 ft with a tribander and 2meter yagis up top).
The shield side of the coax feedline attaches to the mast/tower and the center conductor attaches to both the "dipole" elements, of which one is an approximate 1/4 wave on 75/80 and the other leg is a 40 meter element with an added loading inductor and an additional length of wire ,both totaling shorter than the
80 meter element. I don't know how much the use of a tower improves its operation over a simple mast, it may be considerable, but I have had very good results from it.

Dick W0EX

1183. Re: Copper J Pole in tree for 2M

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 20:21:41 UTC
From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3C4883D5.74E98809@dialpoint.net>
Source record: 150571

When you build the j-pole, leave the ends of the pipe open so water will not collect in the pipes. Then you can drill the hole near the top of the long pipe and hoist it up. Just don't use any metal objects in the hole to hang it with. The rope will be fine. Leave the top of the antenna a few feet below the tree branch. You might also want to let the roap extend past the antenna and secure it around the feedline to take some of the strain off the coax. You may just want to pass the rope through the long pipe and secure it to the coax at the bottom. Just make sure water will drain out so it will not freeze or maybe you can seal the top of the antenna so water will not get in it.

1184. Re: MW Folded Unipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 20:32:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C48866B.D36F2873@eznec.com>
Source record: 150572

You can gain a small amount of efficiency due to the reduced conductor loss in two wires rather than one. Also, the larger effective wire diameter reduces the reactance of a short antenna, which can reduce tuner loss. Exactly the same amount of improvement can be made by simply connecting the same two wires in parallel as an unfolded monopole. In almost all cases, these improvements are inconsequential, and much less than the ground resistance, which isn't improved.

For anyone who believes that folding an antenna reduces the fraction of applied power lost in the ground, do a search at http://groups.google.com for my posting in this newsgroup on November 2, 2001. The subject was "Re: Elevated Feed Vertical Antenna". It shows where the error is in Richard's argument.

Roy Lewallen, W7EL

1185. Is enamel wire needed?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-18 20:52:49 UTC
From: pgardella@yahoo.com
Message-ID: <57d04feb.0201181252.6c0d8613@posting.google.com>
Source record: 150573

I building a Shorty Forty antenna for attic use. (Yes, I know...I'd much rather have a full dipole higher up, but until I can get into the trees, this will have to do!)

Now the big question I have is do I need enamel wire for the trap? I've looked somewhat for #12 enamel wire, to no luck. I have a bunch of hard drawn #12 copper wire here. Could I build the center trap with bare copper? I'm guessing you need the enamel to protect the wire from corrosion, but I'm not that concerned about that in the attic. If needed, could I cover the wire with electrical tape to prevent it from shorting out?

Thanks!

Patrick

Message-ID: <3C488BE4.7CF05E9F@eznec.com>
Source record: 150574

This is deja vu all over again.

Last November, this subject was discussed in some detail on this newsgroup. (See my posting of a few minutes ago on this thread about that.) The paper was mentioned then, too, and the person who brought it to our attention was none other than Richard Harrison. This was shortly after I posted my simple analysis. After the two postings were made, no one put forth any information which contradicted what I and the paper said. The conclusions of the paper are:

"No major differences in field strength between the folded unipole and series-fed test cases were found for any of the configurations tested. The folded unipole was not found to have a significantly better radiation efficiency than the series-fed for a given tower height and ground system. The ground currents for the folded unipole are found to be approximately equivalent to those for a series-fed tower despite the unipole's lower driving point current, which results from a higher input resistance. No major differences in bandwidth were found between the folded unipole and series-fed tower when sideband VSWR was observed rather than simply input resistance. Furthermore, with the wire cage connected to the tower at the top and bottom, the antenna was found to have even wider bandwidth than for either the standard series-fed or unipole skirt-fed tower. . ."

After Richard brought the paper to our attention, I posted:

"Regarding the NAB paper -- it's always comforting when a P.E., PhD, two MSEEs, and a bunch of test equipment and research can come to the same conclusion that can be reached with high school algebra and a little fundamental reasoning. Seriously, though, it is good to see that the careful measurements confirm the fundamental reasoning. It verifies that nothing important was left out of the simple analysis."

Richard, did you not believe my analysis and the conclusion of the paper last November, or did you believe then then but change your mind since?

If you can keep the wires from shorting out then the bare wire will be fine. You can wind the coils with almost any kind of insulated wire but you might have to adjust the turns somewhat by maybe a turn or two.

Like Ralph says, shorted turns are the problem. Over the years there have been many techniques presented for winding coils with bare wire, using cord between the turns, for instance, so that is the only difficulty you will have, other than bending hard drawn copper (ugh!).

Hi Dick,

>
> Mike, several years ago, with winter close at hand and me wanting to use
> 160 during cold weather and with no 160 antenna for it up, I decided to
> put up an ALpha Delta DX-A Sloper, a shortened antenna of the approximate
> size, length and configuration of a 75 meter dipole, that works on 160,
> 75/80 and 40 meters. I figured it would be a minimal antenna but better
> than nothing. In short it turned out to work quite well, and I still have
> it in the air today as a backup, though a few years later I finally got a

I tried an Alpha Delta. I can't remember if it was the DX-DD or
the DX-CC but I think it was the DX-DD because HRO was out of the CC
model and I know I paid about $90 for it. It didn't work worth
beans. I had it up about 25' and I tried it straight and in a L
shape. I had tuning up on it. I even took it up to my dad's place
where he has 3 acres. We hosted it up about 40' clear except for
the 60' tower it was hooked to on one end and the 40' pole on the
other. It still wouldn't tune up very well. I took it home and
rolled it up and stuck it away. I did try it again several months
later during the summer but it still didn't do very well on 80,
either turning up or signal wise. I finally put up some old dipole
that my dad gave me and also I made my own 1/2 wave 10,15 and 20
dipoles that I put up. I put up a couple of 10 meter dipoles so I
could look at two different directions. I've since taken down
everything except the 80 meter and a 10 meter and 15 meter dipole
that I've got using the same center connection. The experience I
had with the one Alpha Delta keeps me from buying another.

> full size 160 meter dipole put up. It does require either a grounded
> metal mast of 30 or more feet, or an existing tower (which I have, 60 ft
> with a tribander and 2meter yagis up top).

I can't quit get up 30 feet. I've got two poles up about 22 feet
on each end of the 75' wood fence we have along the back but I can't
get much higher without being able to guy them. And I can't guy in
two directions (it would go into two neighbors yards). I've thought
a few times of putting in a 6' high 6x6 post buried in concrete and
attaching a mast to it so I wouldn't need the guys, but I've not
done that.

> The shield side of the coax feedline attaches to the mast/tower and the
> center conductor attaches to both the "dipole" elements, of which one is
> an approximate 1/4 wave on 75/80 and the other leg is a 40 meter element
> with an added loading inductor and an additional length of wire ,both
> totaling shorter than the

> 80 meter element. I don't know how much the use of a tower improves its
> operation over a simple mast, it may be considerable, but I have had
> very good results from it.

Another poster gave some suggestions to on how to put a pig-tail
on my 80 meter dipole. I can't quit visualize all of it, but I'm
going to do some more looking into that. I don't have a as much
time to experiment as I use too and now that we are in our rainy
season here in the Northwest, I'm less inclined to install antennas
in bad weather like I once was. <grin>

Thanks, Dick. I appreciate the info. I'll did out my antenna books
and see what I can find in there.

Mike

Ham Radio University 2002/ARRL New York City-Long Island Section Convention

North Babylon, New York - On Sunday, January 20, 2002 at 8AM, the doors of the Babylon Town Hall Annex on Phelps Lane will open for the third annual Ham Radio University. Ham Radio University 2002 is a day of education about Amateur Radio.

This year the forums have been expanded and new forums have been added. There will be twenty, one-hour presentations with special forums geared to the non-ham as well as the experienced ham radio operator. The focus will be "hands on" with many demonstrations.

Come join us at the Babylon Town Hall Annex, Phelps Lane, North Babylon, Long Island, and learn about everything from satellite communications, low power operating using radios as small as a tuna tin, how to put up an emergency antenna, the latest information on advanced digital communications, finding and fixing radio frequency interference problems to purchasing your first station equipment or handi-talkie and a special "Ask the Experts" forum. There will also be a Special Event Station W2V set up and operational on HF. There will live SSTV pictures uploaded to the NLI WWW during the event.

TALK-IN W2GSB/r 146.685 -600 110.9 PL

HRU 2002 is sponsored by the Great South Bay ARC and is a cooperative effort between over twenty clubs and organizations in the New York City- Long Island area. It is also the American Radio Relay League, New York City-Long Island Section Convention. Besides the forums, there will be tables set up with information about the different groups, ham radio classes, exam session schedules, public service and other activities.

Join us for a day of fun and education for the whole family!
Admission is open to all - donation is $2 per person.
(complimentary refreshments available)

For more information contact:
Phil Lewis N2MUN, Chairman, n2mun@arrl.net or call 631-226-0698
George Tranos N2GA, ARRL NLI Section Manager, n2ga@arrl.org or call 631-286-7562

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1503625578

$10.00 minimum bid

This 752 page paperback book is an indispensable aid to working with or experimenting with receiving tubes and was considered the "gospel" of tube reference it's day. Almost every tube known to man is covered showing typical voltages and currents for every pin. Many substitution suggestions are given. Book is in good but used condition. The corners especially and the cover in general shows wear. Binding is in good condition. There is no writing in the book. I absolutely guarantee that this item is accurately described or your $ back! I prefer payment by Paypal but will also accept eBay payments, cashiers check or money order. Inside the U.S., Media mail is $3, Priority mail is $3.95. If you are buying multiple items from me, shipping is only charged on the costliest item, everything else rides along at no extra charge. Outside the U.S., buyers pays actual charges. Note: On customs forms, I will check the "merchandise" box and fill in the final bid price for "value."

Before you go to all that trouble of hanging it from a tree, have you tried it when it is at ground level? Perhaps it will hit all the repeaters and do what you want it to when it is at smack dab on the ground (that is where my homebrew copper cactus j-pole is located and works great for me) .
Don't know if you have tried it there or not but if you haven't, give it a go, you never know.

I haven't tried that (I haven't even finished building it yet) but the
problem is that I have one of the most restrictive zoning boards around,
the XYL! She says that she doesn't want me "junking up our property"
and that there can't be any visible antennas anywhere. If it's in a
tree, facing away from the house, you won't be able to see it. :)

One other option is throwing it up in the attic, building a wood "stand
off" and attaching that to one of the rafters or something. How well
(or not) would that work?

>One other option is throwing it up in the attic, building a wood "stand
>off" and attaching that to one of the rafters or something. How well
>(or not) would that work?

Hehehe....XYL problems....know it well. I have my 2M yagi and a G5RV in the attic, as I'm on a ridgeline I work DX (ok, 2M DX) with it. The j-pole is a bird house..took her a week to realise what it actually was! Birds don't seem to resonate at 50.125 mhz, so no exploding sparrows at present. Try the attic route, it may work well (asphalt shingled roof ok...metal roof?....try loading it up!).

Good luck!
A

A little hard to understand why RCA would include in their marketing and
reference material "on almost every tube known to man."

All the RCA manuals I've had and used over years contained material on RCA
tubes only.

Loose connections have a habit of doing things like that.

My faithful little 20 MHz dual-beam scope that I use for monitoring receive and transmit audio and r-f output envelope signals had worked without incident for over 5 years.

Then, one day the power came on but no traces - just a flash of light and then nothing.

Nothing ventured - nothing gained, so even with no schematic or service manual, I took off the cover to look around before taking it to the shop or replacing it.

Seeing nothing resembling crispy critters among the thousands of tiny parts, I reached for a screwdriver and started tightening every little screw holding down the main circuit board. Every one of them was 1/4 to 1/2 turn loose!

When all were tightened, plugged her in and back to normal operation!

I know - good designs do not rely upon mechanical pressure on PCB ground pads for circuit continuity, but some evidently do.

I have found over many years that a close visual inspection and a tightening of all hardware plus a serious "nose test" for overheated or burned parts will expose and/or cure a wide range of bugs.

That has not been my experience. I have always been able to detect
CW signals when I could not understand a SSB signal. In other words,
just having them switch to CW and continue the conversation extends
the time that the QSO may continue.

Hi Andrew

Many years ago, when I designed the original 'fat' copper cactus, I was living in an apartment, no outdoor antennas at all allowed.

To circumvent this rule, I planted it in a standard terra cotta flower pot, used yellow pixie stix to make thorns and acid washed it to turn it green. The coax was hidden inside of a garden hose, affixed to a dummy faucet which was affixed to the wall to allow the coax to get inside.

Later, using the standard 3/4 and/or 1/2 inch copper pipe, I did the same thing to the base, only painted the pipe brown with light gray splotches and then affixed artificial leaves to it, so that it looked like a regular plastic plant. The only trick to remember is to REMOVE all the wire that is in the plastic stems so they don't interfere with the antenna. If you can get some plastic balloon sticks and some florist tape, you can do a bang up job with the leaves to make it look like a store bought artificial tree.

If you have a tree in your yard with a fork or low angle large branch, you can drill a small hole and stick it in that too, just paint it to match the bark and it will be unnoticable.

TTUL
Gary

> Tightening them down cured the problem.I thought it was RF!
> Long time ago!

This is usually what happens when the neutral is loose. You will frequently find this in houses that use aluminum feeders from the meter to your distribution box.

I have such flickering in my house right now. It isn't in the box, and it isn't high current load. I haven't tried hooking up my Fluke to check the voltage drops yet, but will do that soon. I suspect that it is a loose connection at the meter, the drop at the house or the drop at the pole pig.

You're going to find a shortage of 6-meter ht whips, because 6 meters is
relatively new to ht transceivers. Maybe you need to break down and homebrew
something :-)

Ahhhhh, the aesthetics committee. Know where you are coming from.

She says that she doesn't want me "junking up our property"
> and that there can't be any visible antennas anywhere.

Not even behind a shrub, in a schrub or nicely placed against the
house/tree/fence? I have read the posts below on how to camoflage it and
they sound do able. I would think the biggest eye sore hurdle to get over
is concealing the coaxial cable to where ever you eventually place it, even
in the tree.

If it's in a
> tree, facing away from the house, you won't be able to see it. :)

Hiding the coaxial cable could be a trick thou.

>
> One other option is throwing it up in the attic, building a wood "stand
> off" and attaching that to one of the rafters or something. How well
> (or not) would that work?

Don't know, give it a try. Before permanently installing it and running the
coaxial cable downstairs and so forth, hook the attic located antenna up
to a HT and give it a try. If it works to your expectation, Bingo, you have
a home for your antenna. Same thing for outside installation, carry it
around, place it at possible locations and see if it will even work there,
before going to the aesthetics committee for approval. :) If you have
a metal roof or siding, then arggggggh, you may have a no go in the attic.

Don't know that either. Radios are the darnest things. Sometimes they work well were you don't expect them to and they perform at other times poorly when you think you have a good chance. Again, don't know until you try.

Keep in mind that the longer run of coaxial cable you make from your base radio to where ever the antenna is, makes a negative measurable difference. Keep that run as short as possible. Of course, a good low loss cable brand/type/model can negate most of this issue. On the other hand, if the aesthetics committee just will not allow a close location and you are forced to make a lonnnnng run, then so be.

>
You need to prevent the turns from shorting to each other. You also want the
maximum number of turns in a given space.

Enamel/formvar/polythermaleze insulation is the easiest solution,
but other methods will work. For example, #12 or #14 "plastic"
insulated house wire from Home Depot is one solution, but
you will probably need more turns to get the same inductance.

House wire is often on sale at Home Depot and stores of that type.
Often the "NM" style stuff (typically 2 insulated wires plus a bare ground
wire)
is cheaper than individual insulated wires (go figure). Of course you have to
pull the wire apart but it goes quickly if you have a sharp knife and a good
grip.

I would save the hard-drawn for outdoor antennas.

Tank and trap coils used at relatively high power levels are best wound with spaced turns, the turns preferably being spaced by cooling air rather than heat-insulating plastics. An optimum wire diameter is somewhere between 0.55 and 0.75 of winding pitch. Very non-critical. Choose according to what wire gauge is available.

A construction disadvantage of spaced bare wire is that a groove or slots are needed in the coil former to provide support. Or the coil can be wound with a spacing string between turns - the string being removed after the wire has been secured in some way to the former.

Enamelled wire is ideal for low power coils. But for close wound high power coils a high voltage between adjacent turns may break down the thin enamel

There's nothing wrong with using enamelled wire for spaced windings and enamelled copper wire is much more easily obtained than the bare variety.

If using thick plastic insulation to space the turns the plastic should be of the low-loss RF variety. Take other advice on what to avoid.

Spaced windings also have a somewhat higher Q. So not only is heat better radiated there's less of it to be got rid of.

But the common-or-garden plastic-insulated wires generally have an insulation thickness the same as wire diameter. This spaces the turns TOO far between wire centers and Q will suffer.

For coil design: former diameter, length, wire diameter, number of turns, Q, power dissipated, download program SOLNOID2 from the website below. One smallish file downloads in a few seconds, run immediately. It can be run from the site without downloading.

I've just remembered. For centre-loading of short (attic) dipoles download program MIDLOAD. For a given overall dipole length, this program also designs the coil (size, number of turns) in addition to predicting antenna radiating performance.

A BIG ADVANTAGE of a center loading coil is that it can be matched into either a coax OR balanced feedline by a link winding over the main loading coil. A disadvantage is that a center-loaded dipole is a single-band antenna.

Roy, W7EL wrote:
"Richard, do you not believe my analysis and the conclusion of the paper last November, or did you believe then but change your mind since?"

I don`t remember very well the previous discussions of the folded unipole.

I reasoned that the transmitter is an electrical pump motivating nearly the same number of electrons out of one of its wires as it is taking in on its other wire at the same instant. Thus, an ammeter in either wire will read the same value.

Power is the product of volts and amps. The same power can be high volts and low amps or low volts and high amps. The power lost in a resistor in series with a load is I squared R. High current produces high loss in a given resistance. That is why high-voltage is used for high-impedance power transmission on long-distance power lines.

So, at first glance, it seemed to me that high volts and low amps into a folded unipole would waste less power in a fixed earth resistance than a low-volts, high-amps, presentation of the same power to a base-insulated antenna.

If the millivolts/meter at one mile are the same from a folded unipole as from a similar base-insulated antenna, they have the same radiation resistance. They also have the same loss and efficiency.

The earth resistance is constant, so current in the earth is the same for both antennas. If feedpoint current is different as is indicated by their different drivepoint resistances, some of the earth current is coming from the non-insulated tower base in the folded unipole and adds to that supplied directly to and from the transmitter. The total must be the same as that current supplied directly by the transmitter to the base insulated antenna and ground in that case, regardless of the impedance presented to the transmitter by the folded unipole. I don`t think displacement current differences are significant, or the efficiency could change.

I can change my mind as often as required to fit the best evidence available to me, and my peculiar way of analyzing that information.

Best regards, Richard Harrison, KB5WZI

1215. Re: RCA Receiving Tube Manual #RC-29

"Almost every tube known to man" was likely a boast that the RCA tube line was very inclusive.

Many brands competed and were carried by various suppliers. Several brands were produced by the same manufacturer, who may have also supplied his competitors with types bearing their own brands.

There was seldom a supplier response of "We only carry RCA tubes and that tube is sold only by Sylvania, Tung Sol, Raytheon, Philco, or GE", Most transmitting tubes also had several suppliers regardless of who initiated their designs.

Best regards, Richard Harrison, KB5WZI

When faced with the thought of "the Aesthetics Committee" taking over the world, this is one case where ignorance might be the easiest solution:)
As for me, I've found that conflict resolution can only be achieved by giving the XYL what SHE wants. "Getting in touch with one's feminine side" (nice use of the 3rd person, impersonal is essential so as not to go native:) is a sure fire way to put a bullet straight through the forehead (comment: macho illusion counteracts submission to the feminine side) of the problem and will leave you with a sense of ingenious victory over extreme adversity.
Here are a couple examples:
1) mount the J pole in the front yard as part of a girlish ornament
a. walking stick/candy cane in the hand of a gnome, leprechaun or other fictional creature
b. potted plant hanger
2) buy her that patio set she wants and affix it to the top of the umbrella
comment: yellow fabric with flowers are universally approved of as "sun elements"
3) flagpoles
a. a mast for displaying and rendering honor & respect to our nation's flag
comment: killing two birds w/ one stone. "Do you have a problem with the flag?"
b. let the committee pick one of those decorative flags from Home Depot
4) planted above a birdhouse on a 10 - 20 ft mast.
comment: purple martins, swallows, etc divert the eye to nature vice technology
5) when strung from overhead with the feedline routed out of sight as an ornament
a. wooden windchimes
b. hummingbird feeder
6) erected in plain view, claim ignorance and deny responsibility:)

I don't know about everybody else's situation but my local committee is only knowledgeable about matters of aesthetic beauty. My XYL, though I love her to death, doesn't know what a J-pole is and would have great difficulty understanding why it's "so cool!" She's never complained about the A/C compressor beside the house and hasn't the foggiest clue why we need a breaker box either.
So, when presented with a dutiful husband who did something just for her, she's somewhat obliged to say, "That's sweet, dear". Which leaves me thinking, "Perrrrfect! My plans are almost complete! By this time tomorrow, when I power up my IC-730 combined with the MFJ-949E, I'll extend my electromagnetic forces beyond the horizon and the world will know MY POWER! HAHAHAHAHAHAHAHAHAAAAA!!!"

Good luck & 73's,
Drink, WP3JQ

City Lot =Ant????
Tallest tree is about 25 feet, house is two story. Arrangement makes a
dipole ??

I like to work 40 -15 CW.

I've been looking at 'no radial' verticles

Magnetic Loops - I'd probably build one for 40 to 20 and one for 15 to 30

Brilliant ideas welcome.

tnx

Hey, Reg, crawl off of it, willya? Who cares what the SWR is? What I want to
see if *zero reflected*, or something very near it. I couldn't care less what
the "SWR" is, and over the years I have found that measuring SWR is a very
tenuous way at best to resolve antenna problems. However the ability to minimize
the amount of reflected (voltage, power, call it what you want) is crucial to
the proper operation of any radio transmitting system.
When you see SWR running high it is almost always indicative of some problem
that will also prevent you from being able to get the reflected down to a low

level. And anyone who has worked with transmitters for long knows that what the SWR meter says is merely a relative indication, not numbers to be taken literally. A high SWR reading can mean any of a number of things.

Dick

Confusing feedpoint resistance with radiation resistance is a fatal error made, it seems, by many professional engineers who ought to know better. Amateurs can be forgiven for allowing themselves to be led astray.

That group of so-called engineers/scientists who spent a fortune of somebody else's money to demonstrate radiating efficiency, etc., of a folded monopole is exactly the same as an ordinary monopole should have realised long before they started that use of pencil, paper and elementary analysis would be a much more economical method of ducking old wives.

But then, no-one would have paid them for 2 or 3 lines of scribbled notes ending with QED.

Just another example of the sad state to which Western engineering education has fallen in the last 1/2 century. It is now necessary to occupy the first 6 months of a 3 or 4-year engineering degree course with arithmetic lessons!

Archimedes, Pythagorus - where are you now!

As far as I experienced, RCA never made any Loktals, nor have I seen any with RCA labels which were made elsewhere.

Frame grid tubes were made only by Amperex, but some wore RCA labels.

Nuvistors, on the other hand, were all made by RCA, and I have never seen any with another brand, other than a few OEM radio brands.

6907s were made only by Amperex. I know, as I tried to get a competitor to build them for GE Mobile Radio and bring the price down. Tung Sol tried, and you have never seen a sorrier set of samples than the box of "6907s" they sent us to test. No one else would bite.

There are probably many other examples, but if you want to put the lie to the statement quoted, just put any RCA tube manual next to a GE, Sylvania, or even CBS-Hytron of the same vintage. RCA included curves in theirs, but there were an awful lot of numbers which they didn't even acknowledge existed.

Perry Shankle was a master RCA distributor here, and had a retail parts counter, also. There were a number of tubes RCA didn't make or rebrand, and Shankle couldn't supply. You had to go to one of the other dealers.

Source record: 150611

I checked the unit for obvious loose connections and found that the
porcelain insulator on the output terminal has a crack in it on the inside.
It doesn't go all the way through. It surely isn't a good thing but I don't
think it is causing the tuner to refuse to tune at all. I also made sure I
had 13 volts+ to the tuner.

I pulled all the removable eeproms and gave them a shot of contact cleaner
with no improvement.

As for the led lights, some of them do light up like the "tuned" light and
+5V light when 13V power is applied.
When I transmit, ALL the LED's come on......and stay on while transmitting.
The tuning relays don't "chatter" at all when I transmit but they all
chatter briefly when 13V is turned off.

I downloaded the latest manual from SGC and did the "lightbulb test".
The lightbulb does NOT come on at all, indicating that there is definitely a
problem in the tuner. I know my HF radio is working fine.
I guess the tuner is going back to SGC for rehab!

Thanks for all the help in the newsgroup.

> the proper operation of any radio transmitting system.

Not exactly true. Minimizing the losses is the important thing. For instance, open-wire line feeding a 1/2WL dipole has an SWR of about 12:1 yet that open-wire line will have less loss than RG-8x, RG213, or 9913 with an SWR of 1:1.

> When you see SWR running high it is almost always indicative of some problem
> that will also prevent you from being able to get the reflected down to a low
> level.

My antenna system is designed to run a "high" SWR. If the SWR drops below 4.5:1 on my 450 ohm ladder-line, my matching system won't work. My matching system works for any SWR between 4.5:1 and 18:1. It *depends* on the SWR being higher than 4.5:1 for the impedance transformations.

Assume a 50 ohm antenna on 21MHz fed with 100ft of transmission line. The total losses using RG-8x with no reflected power are 200% higher than open-wire line carrying an SWR of 12:1. The total losses using RG-213 with no reflected power are 100% higher than open wire line carrying an SWR of 12:1. The total losses using 9913 are 60% higher than open-wire line carrying an SWR of 12:1.

It might help to review, "Low SWR for the Wrong Reasons", in "Reflections".

What are we arguing about? We are in complete agreement.
==========
> What I want to see is *zero reflected*,
> or something very near it.
==========
Hello again Dick,

You may imagine you are seeing reflected power but you are not. What line do you have in mind? But again, don't worry about it, it doesn't matter. Who cares what the 'reflected' is anyway?

What you SHOULD care about (and I am sure you do) is whether or not the transmitter is seeing its designated load resistance, usually 50 ohms. And for an hour or two that's the end of the matter. The station shift-duty engineer can go back to reading the comics about CFAs.

Yours, Reg.

The best way to increase the radiation resitance and thus reduce
ground losses, where efficiency is defined by the antenna radiation
reistance /total resistance (antenna plus ground resistance). Folding
the monopole increases feed impedance but not radiation reistance,
since the same current is flowing in the sum of all the conductors to
ground. So to increase the effective length of the antenna and thus
radiation resistace, we want to pit the current node at the top of the
monopole. This and will reduce current losses in the ground. An
inverted L with the horizontal length equal to a quarter wave or a T
antenna will do this as well as a capacitace hat. The inverted L will
have some directivity along the wire and some horizontal polorization.
The T will cancel much of this. Elevated counterpoise radials are also
effective in reducing ground losses without having to bury a hundred
radials. For 160 the have to be pretty high, but 10-15 feet may
suffice.

1230. Ladderline matching/SWR when wet?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-19 20:01:12 UTC
From: googlyelmo@earthlink.net
Message-ID: <3C49D08A.538FC947@earthlink.net>
Source record: 150618

I have a 70' inverted-V at 50 feet [ends at 20], fed with 450-ohm ladderline for 40-10. The antenna is mounted atop a 20' galvanized mast on the roof of a wood frame house, with the line dressed away from the mast >20 degrees its entire length. The included angle of the antenna is about 95 degrees. I use an MFJ-901B tuner to match my Ten-Tec Scout to the line. It is a 2nd-storey installation, with DC-ground to the ground pin of an outlet (checks good, all new wiring in the house).

On 40, everything is fine. But on 10 and 15, I can't get a match, or anything like it (off the scale SWR). 20 tunes sharply, and barely, and sometimes "warbles" when it is really rainy, i.e. the sidetone rises/falls, following along with a quick (<1 sec.) swing of the SWR meter needle. I also sometimes get a little bit of a bite when I touch a metal switch on the rig while all this is going on, so there is some RF feedback going on here. I had a virtually identical set up when I lived in dry Arizona, and it worked very well on 40-20-15-10. But now I live in Seattle, and it looks like I am up against one of the most serious drawbacks ladderline presents, i.e. wetness.

I just put this antenna up 10 days ago, and it has been rainy/foggy/misty (all of the above!) every day since (and likely to be for quite a while yet), so I don't know how this installation will perform dry. Is there anything I can do to bring down the SWR/losses on wet ladderline? I had the idea of treating the line with silicone, but have been advised that may negatively and seriously alter the characteristic-Z of the line, or otherwise degrade performance permanently. Both the line and the antenna radiator check out fine for opens and shorts, and the rig puts out its rated 50W at flat SWR into a dummy.

I have preferred ladderline fed multi-band dipoles up to this point for their versatility and basic decent performance, and I'd hate to go to coax now. I'd like to hear any suggestions and comments, and especially like to hear from anyone who has successfully used ladderline in a wet and rainy climate. Gratefully,

Will, KD7BFX

1231. What does the so-called SWR mtwer tell us

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-19 20:20:27 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a2ckml$10bm6m$1@ID-124126.news.dfncis.de>
Source record: 150470

The SWR-meter is located in the transmission system immediately at the output of the transmitter. It is often housed in the transmitter case itself.

Immediately following the meter is an adjustable impedance transforming/matching network sometimes referred to as an antenna tuner. The SWR meter can also be housed in the tuner case. But compared to a wavelength, the transmitter and tuner are always extremely near to each other with the SWR meter in between.

A transmission line of either coaxial or balanced-pair construction runs between the tuner output and the antenna.

From one frequency band to another, from one end of a band to the other, the antenna input impedance changes greatly from one complex value to another. These large impedance swings are reflected by the antenna back to the transmitter end of the transmission line sensibly unchanged in magnitude.

Transmitters are designed to work into a particular value of load resistance Ro.

Ro is the resistive load into which the transmitter is capable of developing its maximum, undistorted peak output power without exceeding any internal voltage, current or power rating. It is desirable, therefore, for the load on the transmitter to be set to the design value at the start of a transmission and continuously monitored during normal operation.

The tuner's purpose is to transform the wide range of impedances vs frequency, seen looking into the transmission line towards the antenna, to the constant resistive value of Ro required by the transmitter. In modern equipment this operation is often performed automatically, the tuner coils and capacitors being switched by relays or driven by electric motors.

The SWR meter is essentially a 4-arm, RF resistance bridge. Three of the bridge arms are integral to the meter and are fixed in value. The 4th, variable arm is the input impedance of the tuner. The bridge circuit is arranged such that the transmitter is the signal source and the values of the bridge ratio arms are chosen such that the 4th variable arm, the input impedance of the tuner, provides the principal load on the transmitter. The values of the other 3 bridge arms are chosen to minimise power loss within the bridge itself consistent with adequate unbalance detection sensitivity.

Inside the meter the bridge RF unbalance voltage is rectified and displayed on a sensitive (100 uA fsd?) moving coil meter. When the input resistance of the tuner is equal to Ro the bridge is balanced, meter deflection is zero (a null) and the transmitter is then operating with its design value of load resistance. The purpose of the SWR meter, therefore, is to indicate that

this important condition has been or has not been satisfied.

It should be noted, when the bridge is NOT at balance, the meter deflection gives very little information about what the actual load on the transmitter is. There is an infinite number of resistance and reactance combibations which will give a particular off-zero meter deflection and this is further confused by the uncertainty in transmitter RF output volts.

So the meter indicates only whether or not the transmitter load is Ro. But this is all that's required of it. Brightness of a pea lamp would provide the same information just as well if the meter movement and scales were not used for other transmitter monitoring purposes (and sometimes for indicating received signal strength in transceivers).

It should now be clear an automatic tuner must make use of both magnitude and phase of the bridge unbalance voltage to maintain the bridge in a state of balance and so provide the transmitter with its correct load resistance. This conforms to the fact that any impedance matching/transforming device must contain at least two variable components.

Note that the meter movement indicates only the magnitude of the rectified unbalance voltage. Phase information is discarded by rectification.

Also note, for the meter to indicate correctly, it must be designed around the same value of Ro as is required by the transmitter it is to be used with. The resistance standard universely adopted to allow interchngeability of SWR meters is Ro = 50 ohms. So meters generally differ from each other only by their through-power handling capability and operating frequency range. Internal circuitry and physical construction vary widely with frequency range but the basic mode of operation is always that of an RF resistance bridge.

So the SWR meter doesn't actually measure anything. It is a null detector. One thing is certain - there are no standing waves to be measured on the very short connection between transmitter and the meter. However, the meter movement is almost always scaled to indicate the SWR, between 1.0 and infinity, which would occur on a long transmission line of impedance Ro if such a line greater than 1/4-wavelength should actually exist.

By definition, the voltage standing wave ratio, VSWR, on a transmission lne can be determined only by measuring the RF voltage at two different places, spaced 1/4-wavelength apart, corresponding to the maximum and and minimum steady-state voltages which exist on the line. Line impedance Zo and Ro are not involved with direct measurements of VSWR. Only a voltmeter is needed.

Source record: 150471

Will,
What your running in to is just 'normal' for ladder-line
in wet weather. There are a few things you can do, as you've
been told, to 'help', I don't think theres a total 'cure' for
it though. Using something to make the ladder-line shed water
quicker will help. As long as it's applied evenly, and doesn't
attack the dialectric of the ladder-line, whatever it is should
be okay.
The getting 'bit' by RF is another story, I'd think. Changing
either the length of the feed line, or the length of the antenna
will probably take care of that. Something you also might try is
not using the convenience outlet center screw for ground. That
can cause the 'bite' too (depends on the house wiring).
Anyway, it really doesn't 'hurt' to experiment (within
reason),
so give it a 'shot' and see what happens...

What kind of test equipment do you have? Could the cores be any type, or are they likely to be just one or two different types? What size(s) are they?

If all you have is an ohmmeter, you can run one simple test. Put the probes firmly on the core. If you get any reading at all on the highest scale, it's a low-frequency high permeability ferrite like Fair-Rite 70 series or Magnetics J, and not type 43.

If you have other test equipment, let me know what they are and I'll suggest some other tests.

Cecil A. Moore wrote:
"If we were using a class-A amplifier, would we want to tune for maximum power transfer?"

Depends on the desirability of maximum output, minimum dissipation within the amplifier, and what maximum output does to the signal.

Maximum output could be too much.

Power to a class-A amplifier is the same at zero output or maximum output. So, dissipation in the amplifier is input minus output. It runs coolest at maximum output.

Distortion may be a function of output, so you may limit output to limit distortion.

Hi all...

I recently bougth a Handlheld Garmin Etrex GPS. Details at :
http://www.garmin.com/products/etrex/

Studing the manual, i discovered that i could receive my global position trough a serial port of my garmin. And so, as a computer scientist, i though in transmit this information to my web server so i could do whatever i want. But at this point, appears the question...
How its the best way to transmit this information?
Supose i would take it in my car, and i will use a radio, what are the maximum range that i could get?
In case of stoping the car by a remote command, could this (in car radio) receive information too?
The relief of my city is not plan. That are some places that Etrex be "out of service". I have to amplify its signal too.
Considering that i didn't have any infomation about radios, i started to think in my Nokia 6120i celular phone. It has an internal fax/modem and comunicates with the computer trough a serial port.I though it would be easy to use serial comunication bettween the system and the phone but i discovered that Nokia do not publish articles about the protocols. The solution to transmit information could be design a way to make the system "press the buttons" and send messages as emails.
But, how could i stop the car? You can say:
call the phone and the system will detect a phone ring and will stop the car.
Not secure...
Phone ring only four times...
Not secure too...
A good way would be send a cryptographed message to the phone, read it and stop or not the car. But how?
Another way i though, was call the phone, and using it as a modem, send a cryptographed message to the system. Perhaps, this second way would compel the system to have and control a modem what i don't have experience direct with hardware.

And so, the project is based on the steps below...

1 . Choose the best way to transmit the global position or implement one.
2 . Project the main board (I think this step could be done with a litle modification at the minimum 8051 schematics).
3. Write the assembly software.
4 . Amplify GPS antenna.
5 . Project the power suply for all the system.

If you feel yourself able to the job, please mail me at
mreletricus@yahoo.com with your plans and your price.
If you consider this project so easy that you could make it in a few
hours just for fun, send me the project or post it here, you know.
If you have any contributions, please, post it.

Thanks.

Wind on a dozen turns spread around the core and measure inductance with your Autek analyser.

Compare with maufacturer's specification of inductance for that number of turns. If within +/- 20 percent then that's the right stuff.

If you havn't an Autek then determine inductance by resonating with a known value capacitor.

Even if the material is not what you hoped it might be, you can still wind the inductance you want by calculating the number of turns from the value you have just measured with a known number of turns.

Inductance is proportional to the square of the number of turns. Double N and the inductance quadruples.

1241. FS: 58' Tri-Ex SkyNeedle in SoCal

For sale...

Tri-Ex TM-358 Sky Needle tower. Includes 58' three section tubular tower, newly recabled with SS cable, 10' thickwall mast, complete motor assembly for controlled extension and retraction, CDR sized rotator cage assembly, new hinged base, instruction manuals, a 1997 UBC stress analysis, blueprints, and even the side mounted ladder!!!...the whole enchilada ready to
grace your property.

Tower is down and next to my home. It is HEAVY (on the order of 1500#), so it will take a wrecker (I will provide this service) to lift it out of the yard and
onto your car trailer.
To install you will need to (1) manufacture or purchase the re-bar assembly that
goes into
the hole (having it made is recommended due to weight and cost), (2) gather up the 2 necessary gears and thrust bearings for the rotator assembly, and (3)
and lots of labor!! This is not one of those lightweight and flimsy tubular towers!

This is the cadillac of tubular towers. Very strong and rated at 12.4 square feet at 60mph, 7.2
square feet at 78mph, and 3.6 square feet at 95mph while fully extended!! Dead weight capability is 400# including rotor and rotor cage.

Start your new year with a REAL tower that can actually handle realistic antenna loads
yet still be asthetically pleasing to your neighbors.

Pictures available upon request. Email your questions or interest to paul@dock.net

$2495.00 cash, cashiers check, postal money orders all OK.

Located in Thousand Oaks, CA (45 miles NW of LAX).

1242. Half Wave Matching 160m

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-19 21:33:07 UTC
From: Bob G4VGO <rmread@attglobal.net>
Message-ID: <3c49e874_4@news2.prserv.net>
Source record: 150480

I have a half wave antenna I float under a balloon when the weather is right. (About 250 feet of wire at about a 15 degree off of vertical slant)

It is a pig to tune, and I feed it against my normal ground system of about 170 radials of various lenghts (about 2km all together.

What I am wondering is if I should use an elevated counterpoise above the earth system that is shorter than a quarter wave or what does the NG suggest as the impedence is very high and very reactive, making it a real b***h to match.

Thanks

Bob G4VGO

1245. QST contra-wound inductor

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-19 22:52:01 UTC
From: amdx <amdx@att.net>
Message-ID: <IMm28.109885$fe1.1867622@bgtnsc06-news.ops.worldnet.att.net>
Source record: 150481

In the Feb 2002 QST the article on matching short antennas
refers to a contra-wound toroidal air core inductor as being
a method to get very high Q. I've looked for more info, all
I can find is the CTHA antenna.
Is the CTHA the same winding method the author refers
to (contra-wound)?
Wouldn't a contra-wound inductor have zero inductance?

Source record: 150483

Bob,

A 15-degree departure from vertical has no measurable effect. Your 2km of radials are probably an overkill for a half-wave vertical.

If you insist on using something near 1/2-wave just decrease or preferably increase height (length) by 30 feet and try again. Changing height by a few feet will not affect performance.

But the ideal height for really low angle stuff is 5/8-wave = 320 feet. So fly it as high as you can subject to that limit. As height increases above 1/2-wave it will become progressively easier to match to 50 ohms.

You might then be able to work the antipodes on 400 watts at dawn or dusk in March/April and September/October, ie., when the sun is over the equator.

For Heaven's sake, don't even dream about a counterpoise - you will ruin everything.

At night place a neon warning light at the top.

Download program ENDFEED to predict performance and tuner L and C values above a system of radials.

For simple bottom-coil-loading use program BOTLOAD. It will also design the loading coil (length, diameter, turns) for heights up to 1/4-wave and between 1/2 and 3/4-wave. For other heights a series capacitor is needed.

Program L-TUNER calculates L and C values of an L-network to match any pair of complex impedances.

Program SOLNOID designs any single-layer solenoid coil for a required inductance and predicts various performance characteristics such as Q and self-capacitance.

What size balloon, sort of gas, antenna wire ?

Source record: 150486

Hi all,

I'm building an EDZ for 28.4 MHz and I need some advice. All the research I've done agrees that each element should be 0.64l, but they appear to vary on the length of the section of ladder line between the elements and the 1:1 balun. To add to my confusion, I'm using the 600 ohm w7fg ladder line as opposed to the 450 ohm twin-lead all the plans show. I want to use a Quarter Wave Matching Stub made from 75 ohm coax. A unun (Nothing like a little convenient feedline isolation.) will connect the QWMS to the 50 ohm feedline. I don't want to use a tuner for this antenna. Any suggestions based on previous experience would be greatly appreciated. Thanks in advance. :-)

73 de Bert
KC2HMN

BTW, both the balun and unun are Radio Works products. (B1-5K current balun and T-4 line isolator.

1251. how to construct a matching circut for a ramdom wire for 40 meters

I need to match a long 40 foot random wire antenna for 40 meters.
This will be used only on 40 meters novice bands.
The redio will be a emtech nw 40 qrp radio.

1) will I need an antenna analyzer?
2) is there a program to tell me the location and value of the
inductor values which I will need.

3)the antenna will be withing feet of the radio

thanks and 73's

For Sale: 6 Meter Antenna. KLM 50-52-11. Eleven elements on a 30 foot boom. Gain 14.0 dbd, 3db points 21 degrees, weight 27 lbs. Removed from service in sunny SO CA and carefully dissasembled. Includes doccumentation, all stainless hardware and three new spare insulators to replace two cracked ones.
Includes balun made from RG-142. Pictures available. $150 Eric wb6kcn@pacbell.net

1255. Mixing 160 Dipole and 80-10 Dipole on same mast?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-20 04:05:24 UTC
From: Mike Jordan <mjordan@europa.com>
Message-ID: <3C4A4204.6010100@europa.com>
Source record: 150490

I'm looking at getting a 80-10 82 foot dipole (the Alpha Delta DX-CC) and a 160 meter 125' inverted V (although it will be run more as a flat top than a inverted V). I have one corner of my yard that is good to put up a 25' mast and then run two legs of a dipole at 90 degrees to each other. What I would like to do is use the mast for both antennas and run them the same direction. What kind of interaction can I expect from a configuration like this? And what is the closest the two legs can come to each other (as long as they don't touch)? I have built multi-band dipoles before that used the same feed line and plastic spacers that seem to work just fine, so I'm thinking that this will be like those except I'll have two feed lines, one to each antenna center insulator.

As a second part of this question, the inside of the L will be pointing at my two story house that is about 35 to 40' away. That will put the antennas about level with the upper story and my wife's office in the spare bedroom on that side of the house. Is the signal going to be directed in that direction and possibly have a better chance of causing RFI?

Thanks for any help.

Mike

Forget the quarter wave matching stub. I just modeled it with EZNEC. The
dipole should be 41.2 ft long and the 600 ohm matching section should
be 5.7 ft long. I would start with about 6.5 ft for the matching section
and trim it down until system resonance is achieved.

An EDZ works well with a 0.2 wavelength matching section of
ladder-line or open-wire line. It's a good idea to use a
1:1 choke between the coax and the balanced line.

Yes, this happened to me this past summer, took a hit during storm and
lost a/c compressor and color tv. Had electric co. come and check my
meter socket just to be sure (no charge for this) and tech found ground
loose
and not connected to lug (lawn guy must have hit it with tools)
and the hot and neutrals were slightly loose (Al feeds)
tech tightened all up and I used the service report to file claim with
homeowners
insurance.

Call the electric co. and let them check or fix it to be safe !

Perhaps I don't understand your words properly, but......

(1) it is indeed a shortcoming of the program. NEC2 does not understand the concept of non-homogenous ground.

(2) the uniform ground assumption will indeed affect results. I would refer you to some papers of J.R. Wait where he compared results with homogenous / non-homogenous ground assumptions.

==========

If NEC2 understood the concept the program user would still not know what soil values to enter for the various depths. Most people have no ideas even about the top soil. What's the state of *your* back yard? ;o)

A guess by the user of average values for G and K vs depth is good enough for propagation prediction purposes. It is done all the time with EZNEC.

Variations in top-soil properties have only a secondary effect compared with other sources of uncertainty between Tx and Rx. At depths greater than "skin depth" the effects are entirely negligible.

Please, can someone tell me what is the German translation
for "cavity filter"?
Currently I can find a lot of information about that filters but only
in English. As I am a newcomer and a native German speaker
it is very difficult to understand.
Thx
Robert

How well does galvanized electric fence wire do as dipole wire?
Specifically for 160 meters. How well does it hold up?

Thanks

Mike

Mike,
Scrape of the galvanization where you make solder connections
and it'll work fine (although, you'll get an argument about using
'steel' wire rather than copper).
'Doc

PS - Do those 'Bouvier's from Flanders fit on a plate like
the domestic versions?

Beware that coax buried in the ground IS susceptible to lightning. If
lighting hits a nearby tree or the ground, it can conduct to the coax and in
to your shack. I thought that buried coax doesn't need to be grounded. I
found out the hard way that it does.

I'm curious about an aspect of the Radio Works Carolina Windom (approx 136' length) for 160 ops. It seems to me that the vertical downlead from center feedpoint to the lower choke balun (seems like it's around 32' or so of cable) is what is doing the radiating on 160m. Is this the primary radiating element when used on 160m? If so, what we're really dealing with is a top loaded vertical. I guess there is some horizontal radiation too, but more soup probably goes out on the vertical component. Which isn't really a bad thing for 160m work. Many of the commercial verticals with 160m capability aren't a lot longer than 32'.

Actually, it's a 160 antenna that's already put together by a guy
in Texas. He builds them with the electric fence wire with coils
that put the whole thing at about 125' long. I'm thinking of
getting one to give it a try.

>
> PS - Do those 'Bouvier's from Flanders fit on a plate like
> the domestic versions?

No, these are big guys. Originally they were Belgium cattle
herding dogs but like a lot of dog breeds do a lot of different
things now. They still do a good job of herding; cattle, sheep,
ducks, kids, adults, each other... etc. <grin> My other hobby
besides Ham Radio is photographing them. They are highly
intelligent dogs and for a long time I've wanted to do a QSL card of
one gal we have that will sit at a table with her elbows up on it
and have her sitting at my radio like she's doing the transmission.
I think it would be a hoot and a unique QSL card. If I could
ever get my ham table cleaned up I'd do it. <grin>

Thanks for the info, Doc.

I built the cardboard covered with aluminum foil CFA that was described in Antennex a couple of years ago. It did not work well. It is now in a box in the garage.

I would like the CFA to work, but it appears that the claims can not be repeated.

For more information look at the on-line Antennex journal. They have some sample articles on CFA and also look at the Stone Throw column. The editor Jack Stone has been following the lack of results over the last couple years.

www.antennex.com

The Magnetic Loop antenneas do work and I would recommend trying one. Remember that you need really low losses in the loop and tuning capacitor to get good performance.

Keep the two antennas at 90 deg. from each other and you should be able to
feed them with the same piece of coax.

1288. A-99 (Antron 99) using it on HF?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-21 00:16:42 UTC
From: "Keven R. Matthews" <mail@keven.worldonline.co.uk>
Message-ID: <3c4b5de4_1@mk-nntp-1.news.uk.worldonline.com>
Source record: 150424

Antron 99 (Solarcon A-99)

OK I know its heritage is as a CB antenna.. However as I just got HF privledges last week I was VERY keen to get on the air! (10 years on VHF) I already had this antenna up for listening on 10 metres and it says in the booklet that with an ATU it would be OK down to 40 metres.
It is currently about 10 metres off the ground and has the standard A-99 radials (for 10 / 11metres). With the ATU I can easily get a good impedance match indicated by a low vswr reading for 15 metres and had immediate good results with 5 countries in 2 hours, I was happy. However 40 metres is a different story and whilst I can hear plenty and with some difficulty obtain a 'match' for a low vswr reading I have yet to work anyone at all either daytime or nightime. Has anyone any experience of this antenna on HF and 40 metres in particular? Would it help if I was to remove a couple of those 3/8" fitting screw in radials and replace them with some wire radials of different lengths or perhaps increase or decrease the height . Any recommedations / advice welcome (other than get or make another aerial!)

Thanks &

Keven,
The further you go 'under' the design frequency of an antenna, the less well it will work. If your ATU is 'good' enough, you can make a 6 foot wire work on 160 meters, but it will NOT be a very 'good' antenna. The 'A-99' was never meant to work on 40 meter, and will do a terrible job even with a 'Super' ATU. Never believe antenna manufacturer's claims with out a large dose of salt (you can substitute castor-oil for the salt at times)...

Evan,
If your going to use a 'hot stick' for what it was
meant to be used, I would be very, very hesitant about
anything except a new one. A 'used' hot-stick is asking
for a reservation at the funeral home! They aren't cheap
and no one throws one away just because a new model comes
out. Try your local fire department, or power company,
they'll have catalogs, or make one. Just be sure the
material you make it out of has a very large 'safety'
factor built in...

AK9I,
To date, there has been no verifiable testing of the CFA
antenna. None. All the tests have been flawed in some way,
most notably by false measurements (which ~was~ verified).
It would be 'nice' for it to work, but don't hold your breath.

Source record: 150430

Emil,
You have lots of room to play with so getting an antenna
up shouldn't be too much of a problem, depending on where
the supports are localed. The length of a 40 meter dipole
would be something on the order of 62-66 feet, so it would
probably work 'best' running from one corner to the opposite
corner, but could be 'fit' into your area in other ways too.
While the 25 feet height isn't ideal, it will certainly be
'enough' (more is better) to work okay. I'm sure you can
think of a few ways to make things fit better than I can since
you know what you can and can't 'get away' with. 15 meters
should be even easier to make 'fit' (or use the 40 meter
antenna on it too?).
So, good luck with it! I'd be interested in what you
finally do...

> Thanks,
> ak9i

For a Cross Field Antenna, it can be proven that the field strength is about +3dB what can be obtained from a 'normal' antenna. You just need to remember to feed 100% of the applied RF power into the 'E' feed point and another 100% into the 'H' feed point.

Voila.

1296. High SWRs w/ FT8100, HELP!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-21 02:23:53 UTC
From: Danny Morris <dbmorris@mediaone.net>
Message-ID: <ZYK28.367$YT5.122305@typhoon.jacksonville.mediaone.net>
Source record: 150432

I was having probs with my Yeasu FT8100 so I returned it to them for repair (non-swr related-see below if interested). I got it back and reinstalled it. The best I could get was 1.8:1 on 2m and 3:1 on 440. I tried adjusting the Diamond SG7900 to no avail.

So after a couple days when I got around to trying to fix it, I retested and 2m was at 7.5:1, 440 was still 3:1, hummm. I have a second ant mounted just in case and switched to it, same thing to a tee. That is w/ separate coax all the way to the radio pig tail. Any idea what could have happened?

It took them 6 wks to fix it the first time so this time I am not sure I won't just but a different radio (Kenwood TM-V7A most likely).

Help, ideas? I use this in K9 Search and Rescue and need it back in operation.

Thanks,
Danny
http://www.k9alert.org

Problems:
*440 side vol. did not work
*Would not receive distant signals (compared side by side w/ same radio in another vehicle)
*XMIT would hang for no apparent reason
*Display would flash and 'go nuts' or radio would just die
Had several other things but can't recall them all now. Would never buy another Yaesu, their service leaves allot to be desired, to say the least.

Hmmm, I guess I go to plan B then. I've got to install both
antennas in a L shape with one half going South from the center and
the other half going West from the center. I can put one a bit
higher than the other or slope the ends of one down a bit and use
separate feed lines. I was just hoping to be able to eliminate one
of the feed lines I have coming into my house now.

Thanks Bill.

Unless the radio is putting out some harmonics bigtime you may need to check the swr meter. Put it into a good dummy load and see what the swr is. Then check the antenna with a differant rig to see if it is in the antenna.

Graybar sells them. Chance, now a division of Hubbell makes several good choices. Be sure to get the silicone wiping cloths, and make arrangements with your local utility to HV test the stick each time before you use it. And, read the National Electrical Safety Code (ANSI C2- {latest revision year}) for the correct gloves to use with it. And if you have not had the 40 hour lineman's safety course recently, be sure your life insurance is fully paid up and your funeral arrangements are all in place. Electrocution is permanent.

Hi Keven, the A-99 ($38 US) is one of the BEST deals in Ham radio. This vertical's performance is very good from 10 thru 17 meters. In fact in a lot of installations this antenna is resonant on many of these bands. Mine is trimmed for 10 meters, and is also resonant on 15 (1.6 - 1).
As far as lower bands than 17, I do not recommend it, this antenna does poorly on 20 and it is close to useless below that. I would not try any modifications (why mess with a good thing?). Put up a dipole or something like the MFJ ground mount vertical ($160 US) for the lower bands. For less than ($200 US) you would have an effective HF (10 - 80m) antenna farm.

I would like to place a 6 and 10 meter beam on the same boom. About 24 feet long, 5 elements on 10, 7el on 6meters- Seperate coax for each band. Are these compatible with minimal interaction?
Thanks!
Jim W3ATV

1306. Problems operating HF: How much would these improvements help?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-21 05:32:35 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0201202132.35eda53d@posting.google.com>
Source record: 150442

I live in the worst of both worlds: a ground floor apartment at a low land elevation. The QTH is so bad that there is no TV reception, and my AM/FM radio in my home gets fewer stations than the radio in my car. (I was a lowly No-Code Technician at the time I moved in. Also, I wasn't nearly as obsessed about ham radio as I am now.)

Some questions:
1. Do I need a new call sign? Would people have an easier time copying a different call sign? I noticed that people have difficulty copying my call sign not only on HF but on VHF. On the 147.3 MHz Bluemont repeater net (which I check into occasionally), net controls sometimes have difficulty copying my call sign on the first time even when I'm using my mag-mount mobile antenna (MFJ 1724B) or Pocket J-pole OUTSIDE (instead of the ADI/Premier RD-98 HT antenna). The "AG" part of my AG4DG call sign trips people up frequently. I've had people call me KG4DG. There have also been times when people caught the "AG" part but missed the "DG" part. I am in the job search process, and if I leave 4-land, I intend to get a new call sign, as I don't want to endure the bother of adding the "slash-number" every time I give out my call. IF I STAY IN 4-LAND, SHOULD I CHANGE MY CALL SIGN ANYWAY? Any guidelines on what makes a call sign easier or harder to copy?
2. How much does the vertical metal door (which only maintenance staff may open) near my antenna harm performance? This painted metal door is 3 feet wide and 8 feet tall and FACES the antenna. (My patio is an ENCLOSED volume only about 8 feet wide, 8.5 feet tall, and about 6 feet deep - moving my antenna further away would require moving it onto the grass, where it will get in the way.) There's no question that the metal door couples to the antenna - the question is HOW SIGNIFICANT this is. Would things be SUBSTANTIALLY better without so much metal parallel to and facing the antenna at close range?
3. How much does it help to be in a QTH ABOVE trees, buildings, and other clutter? (Even if performance is the same, I'd still rather be on a high floor simply because I would be able to leave my antenna outside 24/7.)
4. If my apartment had a balcony with metal railings, how much impact would they have on antenna performance? When I look for a new apartment, should I look for a place with wood or plastic railings? (I guess it would be a good idea to bring a magnet with me when apartment hunting.)
5. How do I know if my audio is distorting? Do I need a new microphone or perhaps an attenuator? I learned that I need to keep the mic gain on my Kenwood TS-430S down to 2 or less (out of 10) in order to avoid causing distortion. The microphone is an MC-60. I

don't think that the microphone or audio is a problem, as I've tried testing it on local ham friends, and they report that my audio is OK. (I guess I should invite friends over to try my radio and theirs to confirm.)
6. Is my radio broken? I thought of this possibility, but it seems unlikely. People have heard me, and it seems more logical that the QTH problems and my inexperience are more likely to be the culprits of my HF problems. (I guess I should invite friends over to try my radio and theirs to confirm.)

I intend to move as soon as I finish my job search. Even if the new job is local, I intend to move to a better QTH - an upper-floor apartment sitting on land at a high elevation. The upper-floor setting would position me for less attenuation from buildings and trees. Also, since nobody else would have access to my balcony or even close-up visibility of it, I would be able to leave my antenna outside 24/7. I guess I should bring my boombox with me when apartment hunting so I can assess the RF reception of the area and the apartment.

I am seeking employment as an antenna, RF, or microwave engineer. (Any leads would be appreciated.) I owe my future to ham radio, because I would never have been able to understand the technical concepts I studied as an electrical engineering major. Thanks to ham radio, antenna patterns and SWR mean something to me and aren't just mumbo jumbo to plow through so I can pass a class. Although I haven't been homebrewing, attending the Northern Virginia QRP group's lunch meetings has exposed me to practical circuit design, and all the RF/microwave circuit principles I studied (S parameters, oscillators, frequency response, etc.) in school. I'm still busy reviewing my stuff. IT ALL MAKES SO MUCH MORE SENSE NOW!!!

The ARRL people and the ham radio industry will be pleased to hear that I will be spending more time AND money on ham radio in the future. Ham radio will provide me some valuable informal training in my antenna, RF, or microwave engineering career. As soon as I am hired, I will shop for either the Yaesu FT-100D or Icom 706MKIIG (which provides SSB and CW on 6m, 2m, and 70cm as well as HF). I also intend to try out the microwave bands and to homebrew equipment for these bands (as there are almost NO such radios available on the market).

One final note: DON'T FEEL TOO SORRY FOR ME! The HF issues were what initially prompted me to relearn and actually understand antenna principles. If I had no HF issues, I would not have felt the need to review the technical things I studied in school or to gain a REAL understanding of RF principles. However, I do not EVER want to be in a QTH this bad again. Since ham radio is an investment in my career as well as my hobby, I am willing to pay a higher monthly rent for a less miserable QTH.

Jason,
No, you don't really need a new call unless you just want
one. Use these phonetics, " A Guy 4 Dirty Girls ", they may
still ask what you said, but it'll be more fun when they do.
You don't have to use the "/" when you move, as long as
you change your address of record. Most people don't bother
using it anyway since any call sign can be 'from' any call
area any more.
I would imagine that the metal door does affect your
antenna's
performance. How much? Who knows! Try moving the antenna for a
little while and see what difference it makes. You'll have
something to base a comparison on then.
You really don't have to 'live' above the trees, but if you
can get your antenna up there, it will certainly make a
difference
for the better. Again, how much isn't something you can really
predict with any certainty.
What the balcony railings are made of doesn't make much
difference
unless you plan to use them as part of the antenna system
(probably
not the 'best' idea in the world). I would think they could be
used
for suport of the antenna, though, and if the antenna isn't a
monster,
it shouldn't pull the railings down (drop a counterpoise over the
railing).
You have to depend on someone telling you about your audio,
or, as
you suggested, swap places with some one to see/hear for your
self.
There are a couple of 'tricks' you can do to the MC-60 to make it
sound 'better'. Cover the 'slots' on the side of the head to
raise
the tone (get rid of some base tones). And, if you use the
built-in
audio mplifier, do so very sparingly (or better yet, turn it
off).
The MC-60 also has 'ground' problems with some radios. If they
tell
you that your 'RF'y, ground the mic case to the radio chassis
with
a jumper, see if it helps. You can do the same thing by shorting

pins 7 and 8 on the mic plug (audio ground and chassis grounds)
BUT
make sure I didn't goof on the pin numbers first!
I doubt if your TS-430 is broken since the 'locals' seem to
think
it sounds okay. Judicious use of the processor might help. You
can
have too much processing with no trouble at all, keep it off
unless
you just have to use it. Once you have the mic gain adjusted
where
it sounds good, leave it alone! Cranking it up does not make you
louder, only distorted.
Good luck with the appartment and job hunting...
'Doc

Screaming Skull,
For what it's worth, yes. Depends on the tuner, and how
bad you want to be on 6 meters, but sure, it'll work.

>harder to copy?

Much of this is personal choice stuff, aside from that try using the
plain ordinary vanilla Alpha Golf 4 Delta Golf. However, for FM this
is generally considered unnecessary, which indicates deviation
problems perhaps (if not obvious signal strength issues).

>2. How much does the vertical metal door (which only maintenance
>staff may open) near my antenna harm performance? This painted metal
>door is 3 feet wide and 8 feet tall and FACES the antenna. (My patio
>is an ENCLOSED volume only about 8 feet wide, 8.5 feet tall, and about

>that the metal door couples to the antenna - the question is HOW
>SIGNIFICANT this is. Would things be SUBSTANTIALLY better without so
>much metal parallel to and facing the antenna at close range?

If the metal isn't resonant, and it isn't dissipative, then it is
transparent. Since it doesn't enclose you, it cannot shield you. The
wild card here is you do not specify "near" above. Is your antenna
butt up against it, or 8 feet away?

>3. How much does it help to be in a QTH ABOVE trees, buildings, and
>other clutter? (Even if performance is the same, I'd still rather be
>on a high floor simply because I would be able to leave my antenna
>outside 24/7.)

In dB? Just think in terms of line of sight. If you cannot see any
better from the floor above, there is no material advantage. However,
the wild card here is that not all communication is line of sight and
may involve alternate paths that work quite well but are not
intuitive. I've had buddies point their beams west to talk east
simply because both parties could see the same mountain range that
served as reflector to both.

>4. If my apartment had a balcony with metal railings, how much impact
>would they have on antenna performance? When I look for a new
>apartment, should I look for a place with wood or plastic railings?
>(I guess it would be a good idea to bring a magnet with me when
>apartment hunting.)

Wouldn't do much for brass would it? Metal railings would help offer
a counterpoise for many and again if non resonant, doesn't matter
(this all presumes that it doesn't tie into a larger metal structure).

>5. How do I know if my audio is distorting? Do I need a new
>microphone or perhaps an attenuator? I learned that I need to keep
>the mic gain on my Kenwood TS-430S down to 2 or less (out of 10) in

>don't think that the microphone or audio is a problem, as I've tried
>testing it on local ham friends, and they report that my audio is OK.
>(I guess I should invite friends over to try my radio and theirs to
>confirm.)

On extremely rare occasions it can be tones over modulating while
voice level is fine. Something you would only notice with a toned
repeater. However, it sounds like you have a hot mike or your
deviation is set too high.

>6. Is my radio broken? I thought of this possibility, but it seems
>unlikely. People have heard me, and it seems more logical that the
>QTH problems and my inexperience are more likely to be the culprits of

>and theirs to confirm.)

Your having said it twice seems to indicate a possible solution. No,
your radio is not broken (beyond the twist of the deviation pot
perhaps).

Hi Jason,

Just drive around with an HT until you hit the most repeaters and live
in that community.

For work, try www.monster.com and accept that you may have to design
loads before you design antennas (it's a long and winding road).

1313. Help with Ext Power for Yaesu VX-5R?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-21 07:36:31 UTC

Source record: 150454

Any VX-5R Owners?:

Just got myself a new Yaesu VX-5R and trying to run it with
an external Power Supply (Tripp Lite VR-7b,13.8V, Max 7 Amps).

When I connect the external plug to the radio, it shows "charging"
(connectivity to power!!!), however the radio will not let me use the
external 13.8v power supply for "Transmit" (...radio goes dead, and
resets when I pull out the ext. plug)?

Reading the Manual transmit specs (top of page 71) I should be
able to use an External 13.8v Power Supply for maximum 5 Watts
on all Bands power output!

And yes, I double checked; the red is positive at both ends, and
black is ground at both ends, with no shorts (...I even have a
fuse/holder built into the red wire for protecting itself while blowing
up the rest of the components!)!

Gotta be gremlins? Any suggestions?

Robert

Source record: 150452

Hi,
this is stefano Galastri IK5IIR speaking.

I started my experiments on CFA antenna 4 years ago.
the main reason for disappointing results on it is the lack of informations from the inventors.
They have their reasons, probabily, but since the antenna is patented I don't understand why.
Anyway after more than 2 years of experiments I was successfull.
The CFA antenna works but is very critic , complicated, and costs enough money...

Thanks to this big experience I earned a lot of things on this new way to create the electromagnetic wave.
This drove me to the EH antenna concept, my actual interest.

we discussed a lot on this Ng about EH antenna.

I don't want be polemic at all.
I hope in the next future to proof with technical analysis and indipendent labs measurements that the EH antenna is real, works and satisfy all the claims.

In the meantime If you want spend a afternoon playing with the antenna , just experimenting... I am here available to help you to build one of it.
It costs almost nothing, is easy, fast .
In this way you could see with your eyes if works or not.I think this is in the perfect ham spirit.

Sincerly, Stefano IK5IIR

Source record: 150453

Thanks for the helpful advice guys. I wont pursue using the antenna on 40 metres any further. The only other HF band I have at the moment is 15 metres (10 not permitted under my licence class) as I said it worked well giving me fast results but there is an awful lot of static S4 steady 24 hours a day. Without an ATU the SWR reads a unhealthy 3:1 at the moment across 15 metres as it is still at its standard 10 / 11 metre configuration. Obviously with the ATU I can acheive a 'reading' of 1:1.

Would I benefit from changing the radials or adjusting the tuning rings on the antenna?

How did those of you who use the antenna on 15 peak it up?

Thanks again for your advice

1317. Re: Wire Material - Galvanized Electric Fence wire?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-21 12:40:12 UTC
From: David Robbins <k1ttt@arrl.net>
Message-ID: <a2h27e02nl4@enews3.newsguy.com>
Source record: 150457

Galvanized electric fence wire is a poor choice. In many environments it will corrode through the thin zink very quickly and then rust. It is also not a very good steel, it takes very little flexing to break it. I would not use it for antennas any place where ice or high winds were expected, nor in corrosive environments (salt air or industrial areas). For a long antenna like a 160m dipole i would invest in a decent copperweld, flexweave, or another wire meant to be used for long spans.

The radio may be configured to not allow transmitting until the battery is fully charged.

Are there not instructions in your manual on recharging the battery, as well as using an external power supply? Every brand is a little different. It should be covered in your manual.

"stefano" reported:
> the lack of informations from the inventors.
> the antenna is patented

Patents are available on the Internet.

Patents must provide sufficient information to allow a person "skilled in the art" to reproduce the invention. But...

The Patent Office doesn't bother to check if the invention actually works. The only garbage that they throw out are the perpetual motion machines.

A simple dipole (for example) can be very nearly 100% efficient. Can the CFA beat this ? If we have a CFA installed inside a large metal sphere, will the reflections build up energy (being a "better" antenna than a dipole) inside the reflecting sphere until it explodes ? Perhaps you could tap-off sufficient energy at the feed point, by adjusting the mismatch, to power a small city.

A modicum of logic can save a great deal of effort...

I have also used aluminum electric fence wire. It is remarkably
durable.

If you want to buy new wire, I think electric fence wire is the
cheapest you can get (excluding 'new surplus', that is)

Jim
N8EE

P.S. Personally, I prefer American Cocker Spaniels. They fit on your
lap a lot better. I can even get two at once if I try ;-)

Since you already have an antenna tuner, why not construct a small wire dipole, possibly mount it in an inverted-v manner if you're cramped for space, and feed it with tv twin-lead to your tuner? Wouldn't cost much, you could get the materials at a hardware store, and might do a little better in regard to multi-band coverage.

Check with your local telephone company and see if they have any "field wire". This is laid down for temp use when a new line can not be buried or put in place. The stuff is plastic coated and has seven strands of steel wire inside. It is darn near strong enough to tow a car with and of course that makes it hard to work with. Really tough to solder and when wound tight almost acts like a spring. Once you get it up and working however it will last just about forever. Have had 40 and 80 dipoles up for years made from this stuff and have never had a problem. Also make sure to waterproof all connections REAL good.

Sam

The CFA and EH antennas are electrically small antennas that perform similar to most other electrically small antennas of the same size. There is no magic or new physics associated with either of these two antenna designs. Before you believe any "measurements" on these antennas consider the following and ask as many questions about the measurements and measurement setup as possible.

These antennas have virtually no ground plane and they are mounted some very small distance above ground. As a result of this, the feedpoint impedance measurements will be "contaminated" with the effects of ground loss and common mode currents. Anyone measuring the performance of these antennas needs to deal with these issues before they can make any claims about the antenna performance. If they claim that ground loss and common mode currents are not an issue, stop talking to them. A small monopole with virtually no ground plane will suffer from the same problems.

Second, a matching network located at the feedpoint of an antenna does not change the fundamental characteristics of the antenna itself. A matching network does not change the antenna's radiation resistance nor does it change the antenna's efficiency. A matching network allows you to change the amount of power delivered to the antenna system. This antenna system now includes the matching network. Recognize that at a single frequency you can theoretically match any antenna to 50 ohms. A small monopole, the same height as the CFA or the EH antenna can also be matched to 50 ohms with a simple matching network. However, all three of these antennas will still suffer from the same problems. The Q of the antenna itself is very high, which makes it very difficult to match. Small changes in the matching component values will change the measured impedance significantly. That's why all these guys supporting the CFA and EH antenna continue to have problems coming up with measurements supporting their claims.

I'd like to see these guys build one of these antennas at around 500 MHz - 1000 MHz and measure its feedpoint impedance when the antenna is mounted over a large metallic ground plane.

> using it anyway since any call sign can be 'from' any call
> area any more.

I thought that it is common courtesy (for those vying for WAS) to use the "/-number" after one's call sign. Personally, if I leave 4-land, I'd rather apply for a new call sign so I don't need to use the "/" to be courteous.

< I would think they could be used for suport of the antenna, though, and if the antenna isn't a monster, it shouldn't pull the railings down (drop a counterpoise over the railing). >

My antenna is rather heavy - it is the DK3 Screwdriver. If I had a balcony with metal railings, I would connect the railings to the ground plane I use (aluminum foil attic insulation).

< There are a couple of 'tricks' you can do to the MC-60 to make it sound 'better'. Cover the 'slots' on the side of the head to raise the tone (get rid of some base tones).>

I'll try covering those slots with masking tape. How exactly does this help? I'm curious.

< And, if you use the built-in audio mplifier, do so very sparingly (or better yet, turn it off). >

Are you referring to the speech processor? I rarely use it. The mic gain controls the output power. I learned that a mic gain of 2 or higher can cause distortion. Yes, I need to keep the mic gain in the 9:00 position or less. I know now why the "all-the-knobs-to-the-right" crowd is regarded as dorky. Still, I feel that the full power shouldn't kick in until about a mic gain of 8 (the 3:00 position). Adjusting the mic gain is too delicate - too low and I'm QRP, too high and I overmodulate.

< The MC-60 also has 'ground' problems with some radios. If they tell you that your 'RF'y, ground the mic case to the radio chassis with a jumper, see if it helps. You can do the same thing by shorting pins 7 and 8 on the mic plug (audio ground and chassis grounds) BUT make sure I didn't goof on the pin numbers first! >

I might as well give this a try.

"stnapgal" wrote:
"I`m just doing 100 watts CW and the flicker is annoying."

Switching a couple of hundred watts on a circuit of 10X that capability shouldn`t produce annoying flicker. The transmitter power supply has some energy storage to take the edge off sudden demand. The ham with flicker needs to check for a poor circuit or connections.

It makes little sense to use CW in the age of satellites, but AM and SSB can produce flicker too, just not so much. In a SW broadcast plant where I worked, we put a dozen or more high-powered broadcast transmitters on the same program late nights. We skewed the programs to the various transmitters slightly with tape machines to avoid flicker. There was a remnant flicker because our demand was varying by more than a megawatt on a 60-kv powerliine 50 miles long.

Sam, K7SAM wrote:
"Check with your local telephone company and see if they have any "field wire". This is laid down for temp use when a new line can not be buried or put in place."

I bought a mile of field wire on a reel about 50 years ago. It was WW-2 signal corps surplus. It was tough stuff.

About the same time, the broadcast plant where I then worked lost its last mile of open-wire program line in an ice storm. Within an hour or so, Southwestern Bell had replaced the downed open-wire with parallel-wire drop cable laid directly on the ground. We were back in business as normal.

That parallel-wire drop cable is really tough stuff. Of the millions of those coated with ice in the area, very few were brought down.

When the open-wire program line was replaced, the installers asked me if I would like to have the parallel-wire cable they had temporarily used. They said it would otherwise be discarded. I accepted. It obviously makes good antenna wire except for its high visibility.

If the EH/CFA antennas could deliver that much performance in that
little space, they would make the Texas Bugcatcher, Screwdriver,
Isotron, and magnetic loop antennas all obsolete.

If this new type of antenna really were so good, it would have taken
the world by storm long ago.

I'm having fun sleuthing the origins of the log periodic approach to antenna design. I have a pretty good sense of the design origins in the US (at Collins a la Isbell, DuHamel and others) but have been trying to get some details on WWII era efforts in England (which, if true, pre-date the stateside work).

Anyone know details? If so, kindly e-mail, and thanks!

Doc,

I've loaded up my A-99 on 6 and worked *some* DX with it. It actually did
fairly well.
I have also run it down as low as 20 meters, and, yes, it isn't the best for
either band (no-
thing beats a resonant antenna, of course). The "ideal" bands are 10-12-15
meters--the
best being 10 as expected. Like you said, it ain't impossible to work lower
with it, but
it shines on 10.

Are you using the little cheapie adapter that does not have any filtering on it? It's just two pieces of wire and a connector on the end? If so, that may be your problem. I had similar results with mine when using it on a power supply. I wrapped the wire around one of those snap-on cores you can get from Radio Shack and it stopped the problem. Before I did this the exact same thing would happen to me when I transmitted.

The AC mains in the house should be easily capable of
handling
the load -- I doubt that regulation is the problem, and feel
that
it is either RF or a resistive connection (at the breaker
box or
somewhere along the line) due to a connection which has
become
loose -- and hence the IR drop.

Go to the AA5TB website -- there is a pretty comprehensive
set of
articles and links on small loops -- and some good
information on
the capacitors. The loops are simple. but the real secret is
in
the capacitor used.

I was once KG7BK. Hams had trouble copying the "Golf" in my call.
The problem went away when I started using "Germany" instead of
"Golf". Single syllable phonetics were just a poor choice.
I also use "Mexico" when "Mike" cannot be understood.

As I said, this is generally not necessary and indicative of either a
problem with the gear - or the operator. The mistaking of an A for a
K is found in the 'k-k-katie' of the sound which may not be pronounced
enough when you speak it. Record your voice and play it back, can you
copy your call?

Well at 5 - 6 feet, it is roughly halfwave away. That is enough to
disturb the feedpoint Z, but the dynamics of shielding are not total
(at least not like the effect of the standard reflector element).
This should be simply resolved by moving the antenna in experiments
(your being at ground level should offer you enough variation to do
that). Remember to separate the feedpoint perturbation from radiation
coverage problems, they are two loosely related issues.

You've missed the point. Almost everyone's got a line of sight problem. I live in the forest! Trees? I cannot see the horizon nor more than 1000 yards (in one opportunistic direction) without trees in the way, and yet I can hit my buddy's garage based 70cM repeater miles away - with my HT. His antenna is below my horizon! And behind trees, and buildings, and the brow of a hill. Albeit, the HT is iffy and the external antenna solid (or even a ground plane vertical set up in the window).

You and I both can appreciate more gain with higher antennas, but trees and interposing visual blockage of line of sight is not necessarily the end of life. Research knife edge refraction to understand the mechanics of how waves bend around such objects. There are many such edges in life.

If you are 50 feet lower than the surrounding terrain, that says nothing really without context. If 50 feet down a well, yes, you are in deep trouble. If that 50 foot rise is found with a 5% slope, it's more trouble to walk (not much) than to talk over.

Hi Jason,

What with the dot.com failures, many of those RF opportunities were buried in the collapse. Seattle had many RF offerings over the end of the 90's MANY! This is in comparison to 10 years earlier when RF engineering in this region was found only in the big corporations (like Boeing) and maybe one independent research house. I know, because I was part of a spread spectrum design back then. Nearly every one of the recent activity was driven with cellular telephone (AT&T Wireless, this is the home of Craig McCaw's cellular empire after all), or cellular internet connectivity (like Ricochet).

Good luck and 73's
Richard Clark, KB7QHC

Doug finds 1/2-watt carbon composition resistors but needs 2-watt resistors with a value of 500 ohms,

Why not parallel 4 resistors which have a value of 2000 ohms each?

Best regards, Richard Harrison, KB5WZI

1343. Re: Problems operating HF: How much would these improvements help?

Jason,
Your preference of a call sign is exactly that, your
preference. If your dissatisfied with your present one,
by all means change it.
It's been my experience that few people working for WAS
depend on the number in the call sign to determine where
a station is. Most, after making the mistake of assuming
a particular station is 'where' his call sign 'says' he is,
always ask. To be strictly legal, after changing your
address of record, there's no need for the "/". There again,
it's your choice.
The microphone's enclosure, just like a speaker's enclosure,
determines the 'tone' of the audio. By covering the 'slots'
you are decreasing the volume of the enclosure and raising it's
'audio resonance' (it's been almost 40 years since my last
physics class so if the terminology isn't correct, blame it
on CRS). Big enclosures mean 'bassy' sound, small ones are
'tinny'. (If you remove the end-cap of the mic, you can cut
an index card to size, slip it inside the cap and don't need
the 'kloodgy' tape on the outside.)
I didn't mean the processor, but the audio amplifier built
into the MC-60. In most cases it isn't needed, so disable it.
That would result in a need for higher mic-gain, but does away
with the 'processor' type sound. And, as you implied, the
processor on the '430 isn't required most of the time. Since
it isn't adjustable except inside the '430, don't use it unless
you want to adjust it inside.
Good luck...
'Doc
PS - As always, correct spelling is optional...

Irv,
I don't think I'd take either side of that bet! But,
having used hot-sticks at work, and knowing how 'delicate'
they are, why take the chance of someone using one as it's
supposed to be used, and ending up with 'steak fingers'?
The power company has some that extend to over 50 feet, I
hope I never find one that just 'happens' to be laying
around... (I could use another antenna pole!)
'Doc

that is the best reason not to bother with most of these great inventions,
if they really were as good as they claim they would be on the front cover
of major magazines and would be selling like hot cakes, not being debated in
this news group and being sold at ham flea markets.

A dipole is a good first choice but that all depends on what bands you wish to operate and how far the tree is away from the house. It also some what depends on what you neighbors think and if you have neighborhood restrictions.

Assuming you don't have any neighbor problems, and you want to put up something just for 40 and 15, a simple dipole is a good choice. A normal 40 meter dipole, approximately 65 feet split in the middle, will also work quite good on the third harmonic, 15 meters. The SWR may be a little high on 15 but it still works.

If you don't have quite that much space, try a trap dipole. Traps on a dipole tend to shorten the required lengths. I have a trap dipole that works great on 40, 20, 15, and 10 Meters. If you want other bands, like 30 meters, it's not to difficult to add it. The overall length required is reduced by about 20% from the required 65 feet. The nice part about the trap dipole is the SWR is < 2:1 across all of it's bands and doesn't require a tuner.

If you don't mind using a tuner and want all-band coverage you might want to try a G5RV. Lots of information on the net covering this antenna. There is even a shorty version for smaller lots.

> I've been looking at 'no radial' verticles

Look before you leap on this one. Many hams swear by vertical antennas and many just swear at them. So a google search on some of the more popular vertical antennas available and see what the users are saying about them.

> Magnetic Loops - I'd probably build one for 40 to 20 and one for 15 to 30

Like the vertical antenna research this carefully. Many hams use magnetic loop antennas very effectively but they can pose some tough problems.

> Brilliant ideas welcome.

Brilliant ideas? Sure we have lots of them.

1. Buy a book on antennas. A good one to start off with the the ARRL Antenna Handbook. Lots of information on all of the antennas mentioned above.

2. Buy another book on antennas. Actuall several editions. The ARRL also publishes the Antenna Compendium series of books. These are usually article reprints from QST magazine covering various antenna installations.

3. Buy more books on antennas. Yes, again from the ARRL is the Wire Antenna Classics book and Wire Antenna Classics - Volume 2.

4. And last, but not least, ask lots of questions on this news group. There are a lot of very knowledgable hams lurking on this news group. But, before you ask a question, do a search on the google archives. You may find that your question has been already answered several times already.

Not only to stop dimming , but radio's don't like big voltage drops.
Could even cause chirp and other problems in a worst case scenario.
I'd be more worried about the radio performance than lights
flickering. Big amps don't need that problem either. A 100w radio
should not noticeably dim lights on average 15 amp service. I used to
run a pair of drake twins doing 100-120 watts, and an SB-200 all on
the same 15 amp service and had very little dimming at all that I
could notice. I'm sure I had loads of other lower current draw stuff
plugged in also. Thats about 600-700 watts depending... And the
breakers we have are old also. It would be even better with fresh
clean breakers. Running 1300-1400w on 240v , I have no dimming. Thats
about equal to 500-600w on a 117v line I would think. Another thing to
worry about is if the faulty line powers motor run gear like A/C's,
refrigerators, etc, it's hard on the motors, compressors, etc. And
being the current draw is high, where ever the high resistance
connection is , is going to be getting quite hot. MK

Jason here is my spin on things.

Call sign --- the shorter the call sign the easier DX will pick up on it.
I used to be WA6WTO now AC6V.
Noticed a vast improvement when I got my new call in 1977. Next the calls with sharp S sounds punch thru the Pileups ---- K, S,C,T --- worst in my opinion is W ----- da bull you ----- oh spare me. For repeaters, vhf audio restrictions on the repeater or various HT audio may make it difficult for listeners to catch you call. Use standard NATO phonetics until folks get to know you. Avoid funny phonetics at first i.e, Alternating Current Six Volts
Later it may be OK depending on the formality of the repeater.

About the metal door -- get a field strength meter and that may help analyze it.

About audio distrortion on your Kenwood -- most have a MONITOR button -- with earphones listen to your audio here. Some Hams wouldn't know good SSB packed audio if they heard it. get a top notch DXer near by --- they are experts at "good DX Audio" the average ham will tell you to turn off the speech processor, but you ain't gonna break the pileup easily without it. Many hams undermodulate afraid of overmodulating. Get a pro to check you out mic gaun 2, mic gaun 3 etc --- he will tell where you should e. Or use the ALC reading but be aware this might be conservative. Also get some high tones in your audio --- the YL's and kids punch right thru.

If you are interested in DX I have a book on the sbject --- see URL:
http://ac6v.com/DXSAMPLE.htm
Its 266 pages of solid advice with no brag tapes

It covers all of the above in detail. Sorry for the shameless promo but you nay be interested in reading some of the samples. See URL:
http://ac6v.com/DXSAMPLE.htm

Take care and good DX

Hi dear friends,
Yes I understand all and I am agree with all of your objections...
simply you don't have the needed data to judge.

please, I am speaking for the EH antenna only.
This antenna was announced for the first time at the world last
september....is just a baby now.
We are working very hard to start a production, lab tests, indipendent
measurements.

very soon everybody will know about. Please is not an excuse, we just need
some more time.
At the moment is almost unknown...
In the mean time we decided to reveal all about his building
instructions...just for the curious ham loving experimenting.

Thanks, 73 Ik5IIR

==========

Because at HF and VHF, the inductance of the number of spiral track turns on the resistors needed to make a combination of such resistors purely non-resistive, must be quite small. ie., they are of low resisance values.

It is much better to use a number of series/parallel-connected low value resistors, each individual resistor with a few low-inductance spiral turns, when the objective is to obtain a purely resistive high-power impedance near to 50 ohms.

I do hope I have made myself clear.

A few calculations on the back of a cigarette packet, using the antenna's overall dimensions, will show up or disprove any extravagent performance claims.

Let's have some figures or give up smoking !

Otherwise you fall into the category of applicants for patents of perpetual motion machines.

I am only placing minimal emphasis on telecommunications companies.
I'm putting most of my efforts into defense-related companies and
companies that could supply defense companies (components). I know
there will always be demand for antenna, RF, and microwave engineers
in multiple industries. (Fiber optic engineering, my old area, is
primarily used in telecommunications.)

Only if you cannot tune it out. As far as the radiation pattern goes,
it doesn't matter a whit to the other guy. It probably wouldn't
matter if you couldn't tune it out (except for the foldback). If it
is that strong an influence, use IT as the antenna (or at least as a
counterpoise).

You shouldn't mix your discussion of problems so indiscriminately.
The only frequency you've offered was for 2M and tied that very
strongly to line of sight and repeaters - the mention of HF has been
unspecified beyond phonetics and even there in the context of repeater
operation. The voice circuits are wholly separate and different for
VHF/UHF and HF in a mutliband rig. About the only thing you can
confirm is you are talking into the right side of the mike.
Similarly, the antennas mentioned were a mag mount, HT antenna, and
pocket J-Pole (any suggestion of HF?). You call it an antenna farm,
and then later qualify with
>Also, since nobody else would have access to my balcony or
>even close-up visibility of it, I would be able to leave my antenna
>outside 24/7.

One antenna?

>Since ham radio is an investment in my career
>as well as my hobby, I am willing to pay a higher monthly rent for a
>less miserable QTH.
You have written nothing to suggest any miserable characteristics for HF (other than phonetics), but you have pined away about line of sight (hardly a useful topic for HF). Without considerable investment in a tower, vertical with ground field, and/or finding lakefront property, talk of elevation hardly matters at HF and then only if the land rises 20 degrees above the horizon. You aren't going to launch much power below this angle without that aforementioned investment.

Jason, the first lesson of engineering is specification - especially for problems. You seriously need to brush up on this fundamental. When I taught HF systems in the Navy, the six step troubleshooting method (a formal specification of the problem) was drilled into every tech. Critical missions could not afford for problems to persist through browsing circuit points with an O'scope or meter in the hope of discovering the problem. In this hiring environment, you cannot afford to be without the skill of a tech. No successful engineer (unless you aspire to sales or marketing of fractals, EH's, or CFA's) lacks this skill because the commercial world is more cut-throat than the battlefield - the only difference is the red that flows is on the ledger. This difference glares in discussion of those same fractals, EH's and CFA's in other threads where fantasy, hopes, and wishes dominate experiance. Any of my shipborn students (excellant techs, all) would've found a way to stumble and lose these dummy loads overboard during installation.

So when the S/N ratio on the bands drop down to the level where it's not possible to receive SSB anymore, we should all switch to satellites, is that what you're saying? Or maybe we should all turn in our licenses and use cellphones and Internet?

I don't follow your logic.

The type of carbon resistor I usually find is a cylindrical carbon composition with an electrode at each end. As the size of resistors of a given wattage doesn`t vary much with the resistance value, I suppose the resistivity of the carbon composition varies with the resistance val;ue.

I suspect inductance increases with length of a lossy conductor and decreases with the conductor`s cross-section. That`s why I suggested resistors in parallel rather than in series to get the dissipation needed for the application.

If we were concerned with voltage breakdown, we might want to place resistors in series to get the maximum power needed.

Best regards, Richard Hsarrison, KB5WZI

I've already bought the antenna that is made of the wire, but
that's good to know. I'm not in a corrosive environment, although
being in the Northwest, we do get our share of rain. I'll keep an
eye on it and if it kinks and breaks or starts to corrode (and
assuming the antenna works ok) I'll replace the wire parts with
copper clad or something a little more durable. I got it fairly
cheap and at 125' I'll just be able to get it up. I'm not sure how
much I'll be working 160 meters so it's a cheap experiment.

Thanks for the info.

Mike

As I said to David, I got it fairly cheaply and if I have any problems with it over time I can replace the wire part with better material. Assuming the antenna works decent and I find I work 160 meters enough to keep it up.

>
> If you want to buy new wire, I think electric fence wire is the
> cheapest you can get (excluding 'new surplus', that is)

If the coils work, I don't mind buying some good quality copper weld or something like that. I just hate buying a Alpha Delta or something else like that at the price they go for and find out it doesn't work very well or 160 isn't as interesting as I thought it would be. Mostly I'm getting on 160 so I can talk to my dad, who is about 250 miles East of me. He likes 160 and it's a lot less congested than some of the other bands we can talk on at night.

Thanks for the info, Jim.

>
> P.S. Personally, I prefer American Cocker Spaniels. They fit on your

Our Bouviers think they are lap dogs. We have them lining up to get their backs scratched and they think they have to be in our laps for the best scratching. We've got 7 of them and it's when 2 or 3 of them think they have to be in your lap at the same time that it gets interesting. ;D

1363. Condo Isoloop RFI problems - advice? *see web page photos*

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-22 03:37:16 UTC
From: tegwilym@hotmail.com
Message-ID: <efb6d1ef.0201211937.26e97907@posting.google.com>
Source record: 150551

Hello,
I have been experimenting with an isoloop on HF on my townhouse patio.
I was told that if I put the antenna in the vertical position that
the RFI would be reduced. I tried that, but didn't notice much
change.
See this web page for some photos and description of the setup:

http://www.geocities.com/tegwilym/ham/

The loop seems to tune up pretty good with a low SWR, but once I hit
that point (even with just 20 watts) it gets into everything. I want
to clean this up so I'm not blasting the neighbors and screwing up
their phone, TV, radio...etc. then risk getting caught! Of course
being in a condo, I have to deal with all the usual rules.

I just realized that I can probably ground the station pretty easily
since it is next to the water heater pipes. I haven't tried that yet.

Any ideas?

Thanks!

Tom KA7VIK

Kevin, ditch the radials and trim the top down to resonate the antenna to around 28.5 (center) (depending on your installation), while watching 15m for the best match.

Dear Mike, do stop worrying. You won't have the slightest difficulty talking to your dad at a distance of 250 miles on the 160m band, in darkness, at any time of the sunspot cycle, using 50 to 100 watts into any reasonable length of any sort of junk wire. 250 miles is one bounce, up and down, off the good old night-time F-layer. With a bit of luck you might even catch the E-layer just before sunset and just after sunrise. Fascinating at dawn listening to the F changing to the E and then dropping out altogether.

Use a dipole, length = 210 feet or more, or an inverted-L, overall length = 110 feet or more with a dozen shallow buried radials in an average sort of ground.

In full sunlight don't bother switching on the rig unless, perhaps, you can run a kilowatt or more and your local noise level is better than S1 or S2. In full sunlight the E-layer is doing its job at full strength but the D-layer absorbs 160m waves on their way up to the E-layer and again absorbs what's left of the waves on their way down. And 160m groundwaves never get as far 250 miles unless over sea water.

My regards to your dad.

Chip ..

I'm not at my bookshelf, but I think you'll find a complete little section on a fixed log-periodic horn type array in the Jasek 'bible' if I recall correctly. It's either there or in one of the other old time books on antenna engineering on the shelf. Maybe it's in or also in the little old AT&T radio engineering handbook I also have, that little gray one from very long ago and far away. I fergit.

This antenna was first used, if memory is right, as part of the old World War two efforts in the HF radar installations that used the then-new 304TL's in pulsed service to around 30 Mhz and down in frequency as part of the early experiments and initial work on radar looking toward Germany over the channel. If my memory is correct, it describes these fixed direction mast supported arrays as being installed overlooking the Cliffs of Dover. The depiction is a large lowest frequency horizontal pair of wires, two of them forming the top and bottom of a wedge shaped plane of shorter and shorter elements. The top element group of these moved downward in elevation to a point. The bottom element group of these moved upwards to that same point. It created this giant wire beam antenna which was fed from the pointed end which, obviously, was the high frequency end of the array.

If I recall correctly, another smaller version of this approach was a vertical aray which started out tall and got shorter down to a low place at the high frequency end. It, too was fed from that low height point and fire direction, as in the above array, was toward the point. I think gain and other math information was presented for them. I think the text cited that these were in somewhat common use for a few broadcasting sites.

I think it's all under the general heading of travelling wave antennas, which also included a segment or section on the Hadley Fishbone TW antennas as well. Memory says that this antenna was cited in the book as being in favored use by RCA for paths from India to the USA during

World War II and that it was favored by RCA because it had more gain per acre of ground space than the more popular rhombics of the time.

Without going back to the book(s) and being able to look as I type this, I can't cite text, page and so on for you. nor the actual facts as to date of data that is offered.

At one time I even took the times to draw up such LP horn arrays for use at the W5WQN fixed site, based on the designe of placing four such wire monstrosities on each horizontal face of a full sized four square for 80 meters as supports. As horizontally polarized devices, they would have been somewhat (?) minimally invasive into the operating characteristics of the 4 square array, or so I initially thought. Obviously, once you look at the designs, this would have been a 40 meter and upward to 10 meter technique.

Aside from the work to try it I abandoned the idea for two basic reasons. First, if the four square were in the intended fire directions, the fixed log periodic horns would have not been where we wanted to go! Secondly, the height above ground was far too low to produce the low angle radiation desired, as I learned from plotting the things on K6STI's code. My QTH is not the White Cliffs of Dover!

Obviously, I could turn the horns to vertical mode! But in doing that the real intrusion into the 80 meter four square would have been terrible as to loading effects.

Thus the idea died a probably very worthwhile death. Your question involves very worthwhile reading trip into all this for anyone really interested in antennas of all kinds. It deserves a public answer, in my hope to help others here... not a private one.

1372. 160M on R-5 Vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-22 06:04:21 UTC
From: Richard Valentine <rwvNOSPAM@attbi.com>
Message-ID: <Fh738.9128$Qs4.25401@rwcrnsc53>
Source record: 150559

I was wondering if anyone out there knows if I can damage the matching box on an R-5 Vertical by forcing 160Meters on the antenna? I've tried it, after getting a 1:1 SWR through an antenna tuner and I kept the power low (10Watts AM). Who knows where or how the signal radiates, but it actually worked. Made some AM contacts, albeit weak. This is strictly a temporary situation, with a long story behind it. My only concern is, In the meantime will I toast the Matching box on the antenna, or no worries? Till now I've heard varying opinions. Thanks, Rick.

Hi Tom ....a few thoughts...(not in any order)
1. Yes, ground to the cold water pipe inlet to the water heater, should be OK but a 8 ft rod in the ground would be better.
2. Build a balum, (might help, but not supposed to need one) Wind the coax at the foot of the loop (on the ground) ..8 turns x 6 - 8 inches.
3. In the middle picture the loop is positioned the wrong way, point the broadside (you should see the full loop not the edge from the TV (if you could see it)) of the loop (very fine adj..experiment) toward your TV (for testing) later towards your nearest neighbor, also experiment with different heights, the center of the loop is where the "null" comes from, widening (like a cone) as it goes farther away.
4. Close to the fence (4" or so) is fine.
5. Loop works fine 2 inches off ground if necessary (for stealth).
Also you could build a 4 ft x 4 ft decorative box (fake planter ect) with glue (no nails..screws) for the loop with no noticeable drop in efficiency.
6. Use higher quality coax (mini 8) that has much better shielding.
7. Check outside that there isn't electrical conduit or other metal for the loop to magnetically couple to and feed into you condo.
8. Try using 12 & 17 meters..very friendly bands with Very low TVI - RFI.
9. Where is your over the air TV antenna? Is it feed with RG-9? Is there a common complex TV antenna?

73 & Good Luck

I see you chose to disregard my questions. Consider for a moment my example (and I'm sure I'm not an exception - on the contrary): I currently live in a condo where no antennas are allowed, but I did manage to illegally string a 12 m loop on the balcony, approximately 10 feet above ground.

Now, how far do you think SSB would get me even if I were the only station in the world replying to the DX? Don't know? I worked about three times more DXCC entities on CW than on SSB. And now you're gonna tell me that is because CW is "my mode of first and last resort". Most of the DX that I worked was buried in the noise and barely audible, but you would have me believe that somehow all of this doesn't matter. Have you ever had a CW QSO?

I know you have contempt for CW but that is your problem, not everyone's. I am trying to understand what has "the age of satellites" got to do with CW. Therefore, it is only fair to ask the question - do you expect us to use satellites when the spots are down and condx are below marginal for SSB work? It is also not much of a stretch to ask why stop there - if one wants to be on the cutting edge, one should abandon amateur radio altogether in favor of more reliable and much faster fiber optic communication.

I worked CW-SSB about 50-50 when I had better antenna setups (and will again one day) and I equally enjoyed both of them. If you don't like CW - fine with me, but don't pretend that somehow your handicap makes you a cutting edge ham.

I like my horse alright - and as Richard pointed out, very often a horse beats your souped up SUVs without so much as breaking a sweat.

I know what you mean. While we're on that subject, it makes little sense to use:

Sails in the age of boats with motors,
Pianos in the age of Yamaha synthesizers,
Cotton in the age of polyester,
Gas stoves in the age of microwave ovens,
Hardy Boys in the age of Harry Potter,
Cash in the age of credit cards,
Single sideband in the age of orthogonal frequency division multiplexing,
The local hardware store in the age of Wal-Mart,
Religion in the age of paganism,
1965 Mustangs in the age of 2002 Suburbans,
Eyeglasses in the age of laser surgery,
I Love Lucy in the age of Friends,
Actually going shopping in the age of buying on-line,
Hand-quilting in the age of sewing machines,
and Books in the age of word processors.

Anything old is bad. Anything new is not only better, but should replace the old, and nobody should use the old anymore. Cuz it's old. Anyone who does is just, well, old-fashioned, and is holding back the hobby from progressing. How can we progress with a bunch of old guys still using CW on our bands?

I don't know if you will toast the matching box, but I do know that Cushcraft no longer supplies parts for the R5. If you toast it, it's gone, unless you can rebuild it yourself. Might be easier to load up something else with your tuner.

(Of course, you don't want to toast your tuner, either :-)

1378. Directional remote control antenna - Pls help

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-22 14:01:49 UTC
From: "Mike W." <mike@home>
Message-ID: <hhe38.575$8i2.18355@news2.mts.net>
Source record: 150565

Anybody/everybody:

I'm having trouble coming up with a transmitter antenna and "directional-shielding" design for a position-feedback project I'm working on. The problem is that I'd like to use the 75.41MHz-75.99MHz license free (remote control) band which has a requirement that : "An antenna gain not exceeding that of a half wave dipole shall be used". I need directivity from the transmitter in order to limit reflections from nearby objects (which will result in "multi-path distortion" of the apparent signal direction at the receiver). The power limit set for this band (.75 watts) should be way more than I'm going to need for my 100m maximum range, extremely small bandwidth (i.e. CW emission) channel. The plan is to comply with the antenna requirement then use shielding to absorb (rather than redirect) energy which is being emitted in a wrong direction.

I want to radiate a beam which I can rotate from +90 to -90 degrees around the horizon using a rotating platter and stepper motor. A few degrees horizontal and vertical beamwidth (with virtually no side lobes) and 40dB or 50dB front to back ratio would be ideal. At one point I had been picturing a three element "cubical-quad / yagi" of some sort but the polarization of the magnetic component was wrong for the receiving loops (see below). I had decided a dish (or dish segment) would not be practical at 75.55MHz but this was also an initial idea. Both these antennas have a gain greatly exceeding that of a half-wave dipole (i.e. would be illegal) but this is the radiation pattern I'm after.

I have an additional consideration in that the signal is being received by electrostaticly shielded small-loop antennas oriented "edge-on" to the transmitter (within +/- 18 degrees). A loop is a single 12 inch turn (i.e. .08 wavelength) of 12 gauge copper wire suspended inside 1/2" diameter copper tubing by rubber grommets. The tubing is grounded at a single point to provide electrostatic shielding for sharper directional response. This is an adaptation the "Radio Direction Finding Antenna" described in the ARRL handbook (1999, etc editions).

The best idea I've come up with is to use a single turn loop for the transmitting antenna as well. The loop would be mounted on the rotating platter so it could be turned to align the transmitting and receiving antennas in the same vertical plane (i.e. like the primary and secondary windings in a transformer). This would confine the emission considerably in the horizontal direction and would direct a large amount of energy skyward (where reflections aren't a problem) so I'm not in violation of the gain limitation. Just what is the gain of a transmitting loop (either small-loop or 1/4 wavelength) relative to a half-wave dipole? How would I absorb the energy that would be emitted in the opposite direction and in the

substantial front and back side lobes apparent in the radiation pattern for this type of antenna? Anyone got a better idea?

Suggestion appreciated,

Mike Whitfield (VA4MGW)

I don't know if this was meant as a joke or not. In case
it wasn't...

Do you think minorities are too dumb to pass the standard test like
everyone else? I don't! How demeaning to blacks, etc... to suggest
that they need an easier test. If I were black, I'd be offended at the
idea.

Dr. King suggested that men be judged on the content of their
character, not on the color of their skin. I doubt that he would
have agreed with this ridiculous suggestion.

Irv, VE6BP wrote:
"I would almost wager that the reason why any ham would want a hotstick would be as an antenna support."

Broadcast transmitters usually have a number of grounding sticks installed in sites where high voltage can be contacted. These are metal hooks on the end of an insulating stick. The hook is securely grounded through a stout conducting cable.

These sticks are used to temporarily short the transmitter high voltage to ground. This discharges any capacitors. The short remains in place while working on the transmitter to avoid accidental shock from inappropriate application of high voltage to the transmitter.
When the work is done, the shorting stick is removed from its high voltage connection point, and the transmitter is tested.

These sticks have also been turned around with grounded hook in hand to poke and probe at a high voltage point. This is safe regardless of the stick`s insulating properties as long as a flash doesn`t burn anybody.

Best regards, Richard Harrison, KB5WZI

Most tuners will load a two foot antenna on any band with
little problem, but efficiency will be pretty low. As far
as the R5 is considered, I doubt that 10 watts would hurt
anything -- my R7 has an natural resonant reading at 3.52
megs, and I can work a bit with it, bit I only run a few
watts. I have another antenna for 75M anyways. I wouldn't
risk my R7 for something it was not intended to do unless
there was no alternative.

No that happened after they got here, AE chain gangs, rail road work crews,
and other pleasant forms of work provided by them (the rich) for us (the poor).

The tongue-in-cheek reply I gave has this point, the ones that the U.S. owes
are now long dead and gone and repaying a debt to their descendants won't
work. They don't need it any more than I need it. And I don't NEED it.

And no I'm not anti-black either. When it comes down to it we all are/were
immigrants here (forced or otherwise) with the exception of the native Americans
who had the whole country stolen from them. Which is worse the slavery of a
people or the genocide of a people, I think both are bad F.W.I.W.

BTW the original post was a troll to begin with!

The latest archaeological evidence is that the Caucasians were here first.
The oldest known American skull is clearly Caucasian and looked like Patrick
Stewart according to The Discovery Channel.

Hi Tom,
Looking at the pictures on the web sight.. looks like there are not many
options.. couple of things.. yes ground the rig the best you can. Also i've
found that rf travels along the control cable from my small loop. that was
cured by placeing several ferite beads on the cable.. this could the part of
the cause of your problems. worth a try anyway.
Hope this is of some help.

An amateur radio license is a free hand out. The answers to the actual questions are available to you before you take the exam. Why would anybody think it's an accomplishment over and above being able to memorize a few questions?

All the theory needed to decide if the antanna works as claimed or
not, already exists. The tests have already been done. That antenna is
really nothing new in the overall design. Yours just might look a
little funnier than other versions. Unfortunately, the design has
warts. If it didn't , everyone and his sister would be using one
already.
>
> please, I am speaking for the EH antenna only.

> very soon everybody will know about. Please is not an excuse, we just need
> some more time.
> At the moment is almost unknown...

To you maybe...just judging from Steves comments, I'd say he's already
got a pretty good grip on the finer specifics of that antenna. I think
clipping his post and reading it over and over a few times might save
you all a lot of time and maybe even money. But it's your life...:/

P.S. Experimenting is fine. But myself, I don't experiment on ideas I
already know don't/won't work. Would be like driving on ice with
racing slicks. MK

I agree, lowering the standards based on race is an insult to those you seek
to help.

If you (Crt4239) really want to help, instead do it the right way. Find a
school in a district that is primarily in a minority area. Get one of the
teachers to agree to be the sponsor, help that teacher get his or her
license. Then, donate a rig to the school. Come in on a regular basis, work
with the kids, get them interested. Not only will they have fun and maybe
become hams, but they'll get interested in the science and math behind it
all too.

Doesn't have to be a school, could be a boys/girls club, church, daycare,
scouting, what ever. THAT'S how to achieve your goals, NOT by lowering the
standards and cheapening the achievement, solely because someone happens to
look a little different.

By the way, this technique works with ANYONE!

73's,

Robert / N4IXT

PS Yeah, I know it was a troll, but I just can't let it go....

> I need to match a long 40 foot random wire antenna for 40 meters.

Use a simple L tuner. A simple MFJ random wire tuner would work fine, and match nearly anything. You reverse the connections depending on a low or hi Z load. I've had one of those things since about 1978 and it still works. I once got it so hot about 15 years ago the plastic coating on the toroid was bubbling, but it didn't kill it. I tacked a 2nd variable cap onto it later and made a universal tuner. I use that thing as my impedance metching when I run mobile and as a small tuner when portable if I don't feel like dragging my big tuner around.

> This will be used only on 40 meters novice bands.
> The redio will be a emtech nw 40 qrp radio.

40 ft random wires, tuners, and qrp don't really mix very well. If you want a real signal from qrp, put up a center fed dipole fed with coax and use no tuner at all. You can't afford to waste power running qrp. The dipole will eat that 40 ft wire for lunch and spit out the seeds. Also a random wire really should have a ground connection. A dipole doesn't need it. I worked a qrp station the other night on 40m that sounded like he was running 200w. He sure wasn't on a short random wire though...If you are space limited and can't swing the 66 ft dipole, I'd use hi-Q coils and make a loaded version coax fed version. It would still outdo the random wire I bet. Opinions vary, but I've never had very good luck with random wires in general. I sure wouldn't use one for qrp if I wanted any kind of decent signal. Taking a whiz in a whirlwind is not my idea of fun. I've been though this on a few field days until I finally put my foot down and refused to use what I consider as 2nd rate antennas like random wires, G5RV's , windoms, etc. They can keep all that crap as far as I'm concerned. Almost drove me to drinking again with the unpredictable and usually lousy performance. And the goofy part which I never could fathom, is we always had room for full size antennas. Why use anything less in a case like that? I'll stick with my regular old dipoles. Usually coax fed I might add. :/ I only can see using a random wire in cases where you really have no other choice.

>
> 1) will I need an antenna analyzer?

No. I've never needed one of those in my life. Don't own one. They can be real handy for certain things though. They can cause great confusion in many others.

> 2) is there a program to tell me the location and value of the
> inductor values which I will need.

Knowing Reg, I wouldn't be surprised he he had something along those line. He writes so many programs, I can't keep up with them all...I'm sure he will alert you if he does. Actually, from the way you ask that, are you wanting to just add a loading coil to the antenna itself? That would be easy enough, but a dipole would still eat it for lunch. You can use Reg's vertload program to come up with coil dimensions in that case. With a 40 ft wire, you won't need too large a coil. You could also find the values needed for a loaded dipole with that program. Just think of the wire/vertical as one half of the dipole antenna. MK

A tuner is probably the easiest answer. You might get some helpful info on this newsgroup Long Wire Antenna feed point Z. If your qrp is ten watts or less, you might be transmitting in the milliwatts.

Chris- My question is- how did you determine the original length for the
driver, that you then had to add to? Did you use one of the published
"formulas", or a modeling program, or was this a commercial antenna?
What is the size of the driven element (diameter and length)?

With this added information, some answers may be possible.

strange requirements... some off the cuff comments to think about...

to get 40-50db f/b with very low sidelobes will require a very directive antenna, but to keep the gain low it will have to be very inefficient.. my first thoughts would be of a dish, but at the abt 4m wavelength it would be fairly large to get a clean pattern, and would probably have to be fed with a shielded resistor to keep the overall gain low. a slot antenna also comes to mind, but without an array of them the sidelobes would be too large. A horn is another possibility, maybe if made out of a lossy material or by adding ferrites or a lossy dielectric near the feed point the gain could be kept under control, or maybe using a very small feed probe would make it inefficient enough. if none of those work just build the best antenna you can to get the directivity and then add an adjustable attenuator as part of the feed point and adjust it till the field strength is the same as a dipole for a given power input.

That's good to know. I've actually gotten out my old antenna books and done some re-reading on the 160 meter band. Since I never could put up an antenna before, I've not really paid much attention to the how the band works since I got my license back in 1984. I'd forgotten that vertical actually works better for the low frequencies than a horizontal antenna would... if you have the tower or other object to get the height for it.

>

The antenna I'm going to use is a 125' shorty inverted V. I'm not going to be able to get as much "V" out of it as I'd like, but like you said, at night it should work fine.

>

Luckily for daytime I have the other bands to play in.

>
> My regards to your dad.

Thanks. We're both looking forward to getting on 160. He's lucky and has about 3 acres to play with. He had a 60' tower up but a freak circular wind storm came through last year and twisted the top half of the tower and laid it down. With the beam and the wire antennas it came down in the only spot that wouldn't do any damage to their house or their motor home. The only thing hit was the gutter on the house and that was only a few feet of it. The beam was a total loss though. He lost his 160 antenna then but we are going to put it back up now that I'm getting something that can talk on

160. Next spring we'll put his tower back up... actually about 30 feet of it is still up and attached to the big 3 story 100+ year old house that is on the property and is used mostly for storage now. It bent at the roof line. The weather people think they got a mini-tornado through the area but there was not proof of what it was.

Thanks again.

Mike

1407. As a ham, what should I look for in an apartment next time?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-23 01:51:06 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0201221751.1c10033d@posting.google.com>
Source record: 150395

The next time I look for a new apartment, what should I look for? My current QTH is miserable because it is on the ground floor, and the location is at a low land elevation.

I know that apartments are miserable compared to houses. I just want to do better next time. Also, I am more willing to pay extra for a better QTH in the future than I was in the past. (I was a lowly No-Code Tech when I moved into my current QTH. I was expecting a career in fiber optics instead of antennas/RF/microwave. There were so few apartments to choose from, and the nonham issues won me over.)

While being at a higher elevation won't necessarily help for HF skywave, it will help for line-of-sight communications on VHF, UHF, and microwave (a part of the hobby I would like to enter) and possibly even ground wave on HF. I know I also want to be at least 1 floor above the ground, as I would feel free to keep my antennas (especially the more expensive and bulky DK3 Screwdriver antenna for HF) on the outside balcony without concerns about theft. This would be MUCH more convenient. (Obviously, the apartment must have a balcony to begin with.)

So what should I do next time? Some of my ideas:
1. I will try out my Yaesu FT-50R radio and at least listen to all the local repeaters. The more repeaters I can use (especially among those far away), the better for line-of-sight.
2. I will bring an AM/FM radio and see how many local FM and AM radio stations I can listen to. The more FM stations I can listen to and the more AM stations I get during the day, the better.
3. I will also use the AM part of the radio (on frequencies between broadcast stations) and check for noise sources (in case power line problems cause interference).

Are there any other factors I should look for? More importantly, are there red flags to watch out for? (Examples: metal instead of wood railings, metal structures at close range, metal roofing or siding just above a top-floor apartment, etc.)

Jason - the higher up the better. I have WAS (+ 70 sections in the last SS) and 75 countries from my 5th floor apartment with only hamsticks and a 706mk2G. Nothing you can do about all the metal around the balcony - your tuner will take care of it. Definitely want a balcony - external antennas are preferable to indoor antennas.

1409. Bassic antenna power reception efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-23 02:06:31 UTC
From: Richard Corkish <r.corkish@unsw.edu.au>
Message-ID: <a2l5rphhg1@tomahawk.unsw.edu.au>
Source record: 150400
Cross-posted to: sci.engr.radar+sonar,rec.radio.amateur.antenna

I have noticed what seems to me to be a basic discrepancy in the antenna literature and would appreciate your comments. Probably it is just my misunderstanding.

"Antenna Theory Analysis and Design" by C. Balanis (2nd edition) clearly and explicitly states that for a transmitting antenna (at best, with a conjugate match of the antenna to the transmitter) "half of the total power supplied by the generator is radiated by the antenna during conjugate matching, and the other half is dissipated by heat in the generator. (p. 75)". Similarly, for a conjugate match between a receive antenna and its load, "half the power is delivered to the load and the other half is scattered. (p. 77)". This suggests to me that a microwave free-space power transmission system (eg. W.C. Brown, IEEE Trans. Microwave Theory and Techniques, MTT-32 (9), 1230 (1984)) would lose half the input power at the transmit stage and half again at the receive stage, giving upper efficiency limit of 25%. Yet, Brown claims measured DC-microwave-transmission-reception-DC efficiencies exceeding 50%.

Other antenna theory books, such as Kraus (1950), King (1956) and Wolff (1966) support Balanis' position but two others, S.Silver (1949), p. 40 and Ramo, Whinnery and Van Duzer (1994) do not. The latter goes so far as to say (p. 669), "... one would conclude that as much power is scattered under a condition of perfect match as is absorbed in the load. This conclusion is not true, except in special cases where the current distribution may be the same for reception as for transmission."

I'd be grateful if any reader could please help me clarify this apparrent confusion/conflict or point me towards relevant literature.

Thanks in advance,
Dr Richard Corkish

Hi Stefano,

Instead of presuming Mark has no experience with the differences that matter, why don't you simply tell us what they are? ...yeah sure, when pigs fly...

The fact remains that this group or even single members have far more experience than you do with well built, well tuned ones AND the funny versions.

Frankly, you have to convince us that your design is NOT one of these funny ones. The burden of proof is on you. The simple repetition of testimonial just won't suffice as we can offer 10 counter testimonials to every one you thump the tub with.

Simply put, you cannot and have not answered
>Since you know all about it, could you ,please, tell me exactely what you
>tested?And how?
for yourself, Mark is under no compulsion to prove anything you yourself have so utterly failed at.

Stefano, this is a game of denial you are playing. You cannot satisfy the minimal requirements of Scientific American's test for bogus science and you consistently exhibit that with every post. You give no one the impression that will change shortly or even in the distant future. What is worse, you have not added one iota of additional data since your first post some months ago. Personally, I don't have any faith you have accomplished anything.

Get as high as you can -- then you can hang end-fed wire antennas from your balcony or window when it's dark.

Look at the upper architecture of the building -- if there is an attic with crawl space, not only will that keep a top floor apartment cooler, you might be able to string a wire antenna in the attic, and feed it into the apartment below.

Look for newer apartments -- newer wiring and ground systems should be less susceptible to rfi. And give you a better chance of getting a decent equipment ground through the 3rd prong on the plug.

Built-in cable tv outlets in each apartment unit will mean less tvi.

Check the book section at the arrl web site -- they have a few books on stealth and limited space antennas -- might give you some ideas.

And, if you can get right next to a big swimming pool, that may or may not give you some nice signal bounce. Take your ht into the pool, and work the world :-)

The fact that someone else has better privileges than
you or I, does not mean we are entitled to those privileges.
Your salary is bigger than mine - does that mean I should
be paid the same as you? You need to make a better case
to support your point.

Hi Richard,

This is the result of the confusion of matching basis as described by:
Beatty, R. W., "Intrinsic Attenuation," IEEE Trans. on Microwave
Theory and Techniques, Vol. MTT-1, no. 3, May 1963, p. 179
and
Beatty, R. W., "Insertion Loss Concepts," Proc. IEEE, Vol 52, no.

6, June 1964, 663.

From "Microwave Theory and Applications," Stephen F. Adam, published by Hewlett Packard, 1969, pg. 232:
"Considerable confusion has arisen over the use of terms such as "match" and "mismatch," since it is not always clear just what basis is intended."

Such discussion embodied in these tracts are part of the NBS (now NIST) definitions for Conjugal and Zo matches. I would point out that the key word here is "basis" which demands close attention in how they are enumerated in these references. The mid 60's was a transitional era in the usage of these concepts and you are sure to find conflict between sources that bracket this period.

Balanis makes the assumption that the internal resistance of the transmitter consists of a resistor or other invariant resistance, as in a Thevenin or Norton source. This is convenient for analysis and is an accurate representation of a laboratory signal generator, but is not an accurate model for a transmitter. Conventional AM broadcast transmitters, for example, have for many decades routinely achieved significantly greater than 50% efficiency. That is, more than half the power applied to the output stage of the transmitter is delivered to the load. I've personally designed and built CW transmitters with over 85% efficiency. It's because the dissipation is determined largely by the DC resistance of the output device, while the output resistance is determined by the dynamic resistance. (This is, admittedly, quite a simplification.) Tubes and transistors are nonlinear devices in which these two can be dramatically different. (Some have taken to calling part or all of the output resistance of transmitters "dissipationless resistance" but I personally don't like the term, choosing instead to seek explanations that don't require it.)

It's not surprising that an academic person specializing in antennas would make the assumption that "transmitters" are like laboratory signal generators, with which he was apparently much more familiar. But it's a shame that this kind of misinformation makes its way into otherwise respectable books without even cursory scrutiny from anyone who has actually seen and used a transmitter. Any technician ever involved with the adjustment of AM or most FM transmitters could have pointed out at least that the statement couldn't be true in light of everyday experience.

Steve,
I think I'd start out with a 1.5 to 32 Mhz logperiodic. But,
since I doubt if that would go over very well either with the
building supervisor or your wallet, probably something like a
doublet on a low frequency, a vertical, or the longest wire I was
allowed to put up. Considering what the top of that building
looks like (antennas, ac's, other mechanical stuff, a vertical
would probably be the 'best' compromise.

It is a commercial aerial and the length of the DE is 2875mm as givern in the specs in the instruction manual..it is matched with a beta match, they are about half inch diameter and there is supposed to be no tuneing involed....you are supposed to just put it together and away you go....thats what most people do...but not mine (for some reason)......i have tried it with 2 different lengths of cable and evern tried connecting the cable direct to the elements, but still no good...also it seems that the higher i put the aerial the higher the SWR goes...at the moment it is on a pole in the garden about 3 feet from the ground and the SWR is 1.1:1 from 50.33-50.62 but if i put it on a pole at 15 feet high it then goes up to 1.5:1 and then at 30 feet its 1.8:1...it is supposed to be approx 1.1:1 from 49.9- 50.5.....if i lengthern the DE buy about 3 inches it is then 1.1:1 from 50.1-50.3......dont know what happens when i put it up on the pole as i have not tried yet...it got to dark last night.

Source record: 150409

The Yaesu Manual only talks about the charging of the
batteries (...helps sell their charging adapters$$$!) but it does
not specify any special considerations for "running/transmitting"
off a 12 vdc (13.8 vdc) power supply with special connectors!..
...maybe it shouldn't need too, oh well.....

Interesting about the Core!.... does the "Snap on Core" solve an
impedence problem in the dc power wire, sort of like turns in a
telephone cable, where the two wires are cross feeding some
kind of signal into the radio across the DC voltage side of
the power supply (overloading the voltage or current to the radio
for some reason)?? If you know what the core is actually solving,
please explain as I am always learning?

Is the Radio Shack part number for the Core = 273-104?
http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CT
LG%5F010%5F004%5F013%5F000&product%5Fid=273%2D104

or 273-105?

http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CT
LG%5F010%5F004%5F013%5F000&product%5Fid=273%2D105

(I happened to get a free Radio Shack 2002 catalog from the store clerk
this past weekend...anyway, bottom of page 276 shows these types
of snap-together chokes!) Are one of these Core types the one you
wrapped "one or both" of the wires around a couple of times?

Isyour design for the EH antennea available on the web? Antennex maybe?

I would very much like a small antennea like the EH or CFA to work. If you have detailed descriptions of how to build it and how to tune it (probably the most important part), I will try it. Til then, I will stay with my magloops.

I played with the CFA for a couple of months and made several contacts on 40 meters. I got a good 1:1 match and saw some strange hysteretic effects that might have been a sort of phase-lock-in of the field generation. But it did not work as well as my 5 foot vertical with Hustler trap. When Jack Stone of Antennex contacted me when he heard that I had made contacts, I was amazed that my mediocre results were a significant data point.

One of the reasons I like to build ham radio stuff is that I dont have to be perfcet. I can try things that just look like fun, even if there is a better way. And, luckily, I can afford my own time to try things that may not work (on weekends at least, during the week my company insists that my designs work hi hi).

Hi Ralph,
random wires are not very good. I would consider a center-fed
coil-shortened dipole for your conditions. Look at
http://www.g3ycc.karoo.net/4s7nr.html or
http://www.qsl.net/qrp/ant/short80.htm for inspiration. If you want to
calculate one exactly for you, download the HamCalc program by George
VE3ERP (not another HamCalc!), open menu B selection 4 - Short dipole
for restricted space and see.

Hi Jim,
Nice to meet a ham still loving experimenting with no preconceptions....you are a rare person...hi .
So about CFA can be a long chat. I know very well Jack Stone. If you want prove your self the CFA CAN have the same efficiency of a full size vertical (with no traps) you can look for "stefano's cfa experiments" in the antennex archive.
I have completely descript a 40 meters CFA antenna having the efficiency minimum of 70%.
Still today I don't understand WHY very few hams tried to have one built.
I gave all measures, all hints , all....but, I am sure, only three or four hams did it....I know it can be a quite important mechanic job,using some expensive parts...but these behaviors still surprising me.
Of course it can be optimized, and I am still available to suggest you how.

BUT...

The EH antenna is so far superior to it, hence I will be happy to guide you on a complete experiment with it.
You will have a lot of fun and On a simple and fast manner ,you will see the antenna keep his promises.
Thanks , Stefano Ik5IIR

==========

Download program ENDFEED from website below. Enter antenna height and length
and ground system details. Program will predict radiating efficiency, etc.
Also provides a choice of 3 matching/tuning networks - program calculates
L and C values of two L-networks and one T-network.

If homebrewing your own tuner and other coils use program SOLNOID2.

This is one Balanis error.

> for a conjugate match between a receive antenna and its load, "half the
> power is delivered to the load and the other half is scattered. (p. 77)".

This is correct. An incoming wave has a certain
"available power" and a 377 ohm space (generator)
impedance. The receive antenna can, at best,
therefore only deliver the power that is
"available" from the wave, which is one-half the
power in the wave. The rest is re-radiated.

There defititly is something "fishy" here.

This SEAMS to be a problem with the distance between
the radiators and/or radiator(s)/DE. Check this
with Your drawing!
Possible cause: Boom incorrectly put together, one
section turned "backwards", so that the distance
between the elements became incorrect. Or even all
elements mounted in "opposite" order on boom.

Otherwise, talk to the person/firm that sold it to
You, claiming Your money back. It is defective. A
Tonna antenna should work without any extra work (if
not placed at an extreme location)

I agree with Steve; kindly realize that these are questions any AND ALL scientist asks.

An antenna is a finite structure, so it shouldn't take years to address the matters at hand. The last time I checked into this discussion it had gone on for months and months and months.

Perhaps project management would help? Have you detailed your tasks and interlaced them on a time line? This standard practice is hardly infallible but does give one a sense of progress and, more importantly,let's one know what's left to do and how long it should take to do it.

Stefano-
Why do you keep avoiding the issue? If there is any basis to your
claims, there must be data to back them. You say you measured 70%
efficiency on a CFA, and that the EH is better.
answer these, if you can.
1. describe what you made.
2. describe the tests you made, and the parameters you measured.
3. describe the method and instrumentation used for the tests.
4. give the results of the measurements.

otherwise- all your claims are junk.

Richard Corkish wrote:
"half of the total power supplied by the generator is radiated by the antenna during conjugate matching, and the other half is dissipated by heat in the generator."

True in the case where the signal source is continuoous. We know that power flow in a Class C amplifier is not continuous, but is drawn in pulses from the power supply.

Power output from the transmitter is continuous, never-the-less, because there is a tank circuit which continues to supply power during the switched-off periods of the Class C amplifier. If you have scoped the transmitter output, you know the waveform is pure as required by regulations.

Source opposition to current can take the form of an open switch. Zero current flow produces zero dissipation.

In many Class C amplifiers, current flows for only 1/3 of the r-f cycle. 2/3 of the cycle, power output of the Class C amplifier is switched-off. There is no power loss in the Class C amplifier while it is switched-off.

During the 1/3 of the r-f cycle while the amplifier is conducting, it is switched-on hard and fast. The amplifier has a very low voltage drop and power loss.

Internal opposition to power output in a Class C amplifier comes mostly from its switched-off time which is lossless. What loss the Class C amplifier does have comes from the internal voltage drop across its switch while it is conducting. This voltage drop is small and so is the power dissipation.

The apparent output resistance of the Class C amplifier comes from the average internal resistance seen over an r-f cycle.

If there were no internal switch and circuit resistance, a transmitter might have 100% efficiency. 70% or so is typical. This high efficiency is obtained because most of the internal opposition to power output comes from open-switch time which is lossless. This opposition to power flow as produced by an open switch is appropriately called "dissipationless resistance".

Best regards, Richard Harrison, KB5WZI

Bill, W0IYH wrote:
"for a conjugate match between a receive antenna and its load, "half the power is delivered to the load and the other half is scattered. (p77)" This is correct."

I don`t like Balanis` use of the word "scattered".

The source resistance of a receiving antenna is its radiation resistance. The voltage induced in the receiving antenna appears in series with the antenna`s radiation resistance as a generator feeding a receiver load resistance, disregarding reactances for simplicity.

If the load matches the source, there is no reflection from the load. Half the energy is absorbed in the load. The other half of the energy is lost in the radiation resistance of the antenna. It is re-radiated (scattered?).

Best regards, Richard Harrison, KB5WZI

==========

But if the output ('internal' is better) resistance is not known, and how to obtain/calculate it is a mystery, it is not needed for any recognisable purpose and it doesn't matter what it is anyway, why waste bandwidth waffling about it ? ;o)

Bill,
I am afraid you won't get any defendable figure out of them (at this time, at least)... apart from unsupported assertions like "it performs like a full-size dipole", or "the efficiency is 95%", or "somebody has worked New Zealand in 40 m" etc. etc.
The ONLY proper and independent test (that failed..) has been carried out by Ted Hart at 1540 kHz. This was happening in October 2001; we have heard nothing since... his Web site is just silent !
One wonders: how comes that it is taking so long to make the EH antenna work properly at MW frequencies ? Is it more difficult then expected ? Why ?
Oh, I can see it coming.... now Stefano will tell us that - with time - this antenna will storm the world of low frequencies, it is just too early, etc etc. ... good luck to them... I will wait for independent (and trustable) tests.. till then, sorry, but I just cannot stand snake oil !

Michele IZ2EAS

I am still trying to find out if Paul Williams' lovely book " Antenna Theory and Design" (vol 1 pub 1966, Pittman, London UK) had subsequent volumes and am eager to see if anyone has access to these. So far, in a somewhat leisurely and long-term fashion, I have failed to either find a copy of the later volumes, nor found anyone who has heard of them.

Any help?

Thanks!

This is generally the case for most antenna structures. However using
clever design techniques, it is possible to deliver (nearly) all the power
from an incident wave into the load (without enclosing both source and receive
antennas in a metal box).

Source record: 150336

In an antenna installation does the type of mast used make a difference in how the antenna performs? I've got a Cushcraft AR-2 2m ringo in my attic attached to the floor of the attic with an antenna mount and a piece of PVC pipe holding it up. However, I have thought about switching it out with a piece of metal mast pipe I have laying around. Will doing this change anything about my antenna at all? I am mostly concerned with TVI which I have somewhat of a problem with but if this will hurt or improve anything I would like to know that. Any suggestions are welcome. Thanks!!

1449. Any experience with the SteppIR Yagi?

Hi All,

There is a mechanically adjustable Yagi called the SteppIR antenna. The web site is www.fluidmotion.ws. It looks like a great idea. Does anyone out there have any experience with it? I would love to get your feedback.

Thanks,

Tim Henry AB0RI

Reg wrote:
"But if the output ("internal" is better) resistance is not known, and how to obtain/calculate it is a mystery, it is not needed for any recognizable purpose and it doesn`t matter what it is anyway, why waste bandwidth waffling about it?"

I find only one point of agreement above. Internal resistance is less confusing than output resistance.

Internal resistance can be determined.

Internal resistance limits output.

Some amateurs want maximum output from a transmitter, which may or may not be the same as the rated output.

Maximum output is obtained with a conjugate match. This does not mean an equal power is being dissipated in the transmitter as is being fed to the load because some of the internal resistance of the transmitter is of the non-dissipative variety.

Best regards, Richard Harrisomn, KB5WZI

Source record: 150339

Greetings,

Sometime in the next few months, before it gets too hot to climb the tower, I want to put my A4S (20/15/10 4-ele beam) back in the air. It worked fine when I took it down, but has been in pieces laying on my roof for several years, and some of the traps are showing signs of cracking on the end seals.

Although they have not been exposed to standing water, it's possible that moisture could have crept in. I'd rather not dissemble them unnecessarily, so am looking for a way to test them as is.

I have the original datasheet for the A4S but it does not include any details. Neither is Cushcraft forthcoming with anything useful (not that I would really expect them to under the circumstances). I expect each inner trap to be a parallel-resonant circuit at 28MHz, and the outer ones to be resonant at 21MHz, but that may be too simplistic. I'd also like to get some assurance that the power handling hasn't been degraded, even though I probably wont be running much over 100w.

I have a good selection of test equipment, I just need some ideas as to what exactly I need to look for.

All suggestions welcome.

Hi Stefano,

It appears you need remedial instruction from Scientific American's
skeptic:

>1. How reliable is the source of the claim?
figures they cite are distorted, taken out of
context or occasionally even fabricated.

>2. Does this source often make similar claims?
since the beginning, and to no obvious evidence.

>3. Have the claims been verified by another source?
They CAN NOT verify it themselves!

>4. How does the claim fit with what we know about how the world works?
It DOES NOT, and we are offered alternative math to prove it.

>5. Has anyone gone out of the way to disprove the claim, or has only
>supportive evidence been sought?
This group, like the fractalists (my spell checker, certainly more

scientifically rigorous that this sect, insists the word should be fantasists), simply ignore bad news; as far as supportive evidence goes, see #3 above!

>6. Does the preponderance of evidence point to the claimant's
>conclusion or to a different one?
Again, see #3 above! This group ignores outside data, and has to rummage through junk science for a rubber crutch.

>7. Is the claimant employing the accepted rules of reason and tools of
>research, or have these been abandoned in favor of others that lead to
>the desired conclusion?
Again, like the failed fractal debate, these nostrums for the curious serve only to satisfy those "in search of ancient mysteries."

>8. Is the claimant providing an explanation for the observed phenomena
>or merely denying the existing explanation?
>This is a classic debate strategy--criticize your opponent and never
>affirm what you believe to avoid criticism. This stratagem is
>unacceptable in science.
This is a classic move from the failed fractal debate too. Stefano tried to pull it on Mark just two posts ago.

>9. If the claimant proffers a new explanation, does it account for as
>many phenomena as the old explanation did?
Well, perhaps Stefano is not guilty of this staple from the fantasy of fractals. Clearly the best defense offered here is simple ignorance cloaked in the fake mumbling.

>10. Do the claimant's personal beliefs and biases drive the
>conclusions, or vice versa?
Again, the hubris of fractal delusions emerges as the operative factor.

Stefano, even with the allowance of #9, you have hit 9 out of 10 to register 91% efficiency in BALONEY generation. This is exceeded only by fractal BALONEY which tips the scale at 1100%! (forgive me for using fractal math, so useful in cooking the books of claims ï¿½ la ENRON/Anderson). By the way, it takes only one hit from the list above to commit CFA, EH, and fractal trash to the science dustbin.

I wish Jim good speed and reward to his effort, and the hopes he will not be ignored by you as a buffoon if/when he reports on the sad numbers that reveal the depth of loss that attends this design (see Scientific American's rules #3, #5, and #6 above).

But not to scare you away Stefano (I see another ghost trying to resurrect himself like Nixon ;-). The group appreciates your impression of Chico Marx. Nothing so amuses (beyond the inflated ego of fractal science (sic)) as these hick routines of aw shucks we're just good ol' boys mixed with the shuffling paisano fruit peddler. If you only had a phD (sung to the music of the tinman in the Wizard of Oz). You need credentials like teaching remedial electricity in a

Home Economics college.

Given the complete lack of hard evidence, it is obvious why this paisano act is so well polished. This, like the failed fractal debate, reveals why data is the first casualty and science finds itself prostituted for commercial gain and ego satisfaction.

Seriously, on 160 meters (actually, anything from 6m on down) galvanized, aluminum, copper, steel, damned near anything will work for a narrowband antenna. And suppose it rusts? Iron oxide is a fairly good conductor, and for those that worry about skin effect, go calculate skin effect depth at 2 MHz..

Help
I have a Racal ATU from an HF navigation system, it's unbalanced in and out in the form of an autotransformer with 11 input and output tappings with one or two vacuum variables (8-650pF) across the whole coil which consists of 35 turns on a 2.5" former. I believe it's designed for the lower HF frequencies and perhaps to match to a short vertical. The configuration and use of an autotransformer isn't something I've seen in the amateur literature - I'd appreciate any comments as to it's capabilities and drawbacks as I'd like to use it or modify it for general HF use. The unit is very well built with EHT cable and incorporates a 5A RF current meter driven from a transformer in the output line.
Any comments/suggestions appreciated.
Thanks

John

Skin depth is small compared to typical zinc coating thickness of new zinc covered wire.

Nevertheless, the resistance of zinc is around 350% of copper, so the ohmic loss of the wire will be higher than an equivalent copper coated wire, but if the wire is not too thin, it won't matter too much.

My estimates using Reg's WIRESKIN calculator, and adjusting for resistivity and permeability, are that you are probably talking additional loss of the order of tenths of a dB for practical wire sizes. In a practical sense, selection of the transmission line is probably more important.

Reg, have you though of adding input fields for rho and mu, so as to model gal wire, stainless elements, aluminium etc?

> deed restricted you can put up what ever you wish
>
I agree that a house is MUCH better than an apartment. However, I am
not ready to buy a house yet. And the mortgage excludes many expenses
that rent does include (property taxes, maintenance, etc.) and is thus
misleadingly cheap. Then there are the issues of the debt, the
possibility I could move again, and the risk that the property value
will go down. (I know financial history - rising asset prices are NOT
a constitutional right upheld by the Supreme Court.)

I know that if I follow my own suggestions and those provided by
others in this thread, I can have a vastly better QTH, even in an
apartment. I'm not saying that an apartment is a good QTH - I'm just
saying that my current QTH is a MISERABLE one, and simply insisting on
a few key characteristics in my next apartment will be a VAST
improvement.

Now, if you're willing to lend me a few hundred thousand dollars with
no fees and a 1% interest rate, I will buy a house and enjoy QSOs on
the air with you. :)

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C4F1CAD.825A0D83@eznec.com>
Source record: 150353

A scale model CFA was measured in a laboratory and the results reported in the September 2001 issue of the IEEE Transactions on Broadcasting in "Short Medium Frequency AM Antennas" by Valentin Trainotti. He found it to have the same performance as a vertical of the same height, if he kept the "D plate" open. When he excited the "D plate" as the inventors recommend, the efficiency dropped appreciably due to losses in the phasing network. These results are completely consistent with theory, modeling results, and experiments reported to me by private correspondence.

The main difference between the CFA and EH antennas, as far as I can tell, is that the EH antenna requires a magical inductor having a 90 degree phase difference in the currents at its two terminals. I'm still waiting to see one of those!

I quoted a concluding paragraph from the Trainotti paper in a posting to this newsgroup on December 19, with the subject "Re: any info about EH?". You should be able to find it at groups.google.com.

(The following is provided as an opinion only, and without warranty of ANY kind. You take all the risk. If you are NOT comfortable doing this job, STOP, you may ruin your antenna. That being said, my own results have been very good...)

Hi Alf;

I was in the same situation as you when I embarked on a project of A4S testing and recovery. It's been a long slow path, but the end result is very satisfying. The unit I have includes the 40 meter add-on kit.

As you, I found that the "support" at Cushcraft amounted to little more than a junior employee telling me he didn't know of any trap problems...YEAH RIGHT!

You need to decide what makes the most sense for you. You can properly restore the antenna, or try to band-aid it hoping for the best. If you do the latter, depending on your weather and climate, you will likely see regular trap failures, partucularly in wet or icy conditions. Sometimes they will clear up when things dry out again, but sometimes you can get internal arcing or opens, in which case the only remedy is to bring the whole antenna down and work on it. If you don't mind doing this every six months or so, then you're more energetic than I.

The resonant points of the traps are neither intutive nor easy to measure with any certainty. In my experience the best approach to dealing with this antenna is to open up EVERY trap and give it a thorough going-over (described below). If you do this, then the chances are very good that you've got at least several years of worry-free operation, hurricanes notwithstanding.

So here goes:

1. During disassembly, mark each trap according to its type, TA, TK, etc. with a black magic marker on the outside of the metal can. Also draw an arrow -> pointing toward the boom (this is not really necessary, but can help avoid a backwards mounted trap).

2. Pick a trap to begin with and remove the end caps. Note whether they are cracked or dried. (You'll want to order a bunch of replacements from Cushcraft, be sure to order a few extras.)

3. Notice that the trap has on one end a region of the can that has been stamp-formed inwardly, and has a screw attaching it to the element tubing (remove this screw and save it). The other end of the can has a few dimples that have been impressed into it. These dimples

rest in a groove in a spacer doughnut inside the end of the trap, and will make disassembly very hard.

Now for the tough part...

4. Using only as large a drill bit as necessary, drill out all of the pesky dimples. Don't drill any deeper than you have to, you just have to penetrate the aluminum can. Yes, this drilling will very slightly change the capacitance, but experimentally it hasn't seemed to matter. It's best to use a drill press for this step so you can better control how deep you go. Now, the discovery...telescope the trap "guts" and the spacer doughnut out that end of the trap, and see what's inside (for better or worse)!

5. Inspect for insects, dirt, arcing or burn marks, etc. Clean up the trap contents, but do NOT use any solvents nor abrasives on the body of the coil. In most cases a soft bristle brush and a vacuum cleaner will do fine. Compressed air is also a help.

6. Notice that each end the coil is fastened to the tubing with a thread-cutting screw. This interface is where most of the contact problems occur, due to the copper-to-aluminum interface.

Here's the messy part...

6. Remove each coil-end screw (2) and observe if the screw itself has rusted/corroded warranting replacement. If so, get a stainless screw of the same design and size. Now lift the end of the copper coil slightly and abrade the two contacting surfaces (one copper, one aluminum) using a fine grit double sided emery file (or a diamond-dust double-sided nail file). You can also clean up the top of the copper wire (just at that point) so the screw will have a clean contact area to clamp onto. Using Penetrox-A, grease up all of the contact areas thoroughly, and tightly reinstall the two hold-down screws (don't strip them!). Work clean, keep a clean rag handy, and be careful not to get Penetrox on the coil windings, nor anywhere else for that matter (not easy).

7. Reassemble the trap. Using a similar approach, abrade and grease up the contacting surfaces where the screw removed in step 3 goes. Replace this screw with a new one if it's badly corroded, tighten well but don't strip.

8. Replace the plastic end caps, either with your originals (if intact) or with new ones. Now, ohm out the trap, you should see a small fraction of 1 ohm, in other words a DC short. If you see any appreciable resistance, something's wrong, don't continue till you resolve it.

9. Repeat with all traps.

10. Reassemble the antenna, putting a layer of Penetrox-A in each of the tubing joints prior to insertion.

Once you do this, and get the antenna tuned up to the band centers you like, it should be very stable for a very long time.

Note: If in this process you find one or more trap coils that appear to be heavily coated with carbon powder or residue, you've got an arced-over trap that needs replacement. This can be the result of too much power, an insulation failure, or using it on a non-supported band (such as 17m).

Hope this helps.

P.S. On my A4s I still occasionally see some motion of the resonance center point in icy conditions, what I understand is that the ice makes the antenna look electrically longer, thus the resonant frequency decreases until the ice melts off at some point.

Mike Jordan wrote:
"How well does it hold up?"

In Tierra del Fuego, Argentina galvanized steel fence wire is used for telephones. It doesn`t rust out. Bare steel doesn`t rust much. It`s too cold. Winds are usually hurricane force. Wind is so prvailing that the airport shuts down when the wind dies down. The runways are too short for commercial traffic absent the wind. The airport seldom must close.

The main telephone line between Rio Grande and San Sebastian is one galvanized fence wire nailed to poles alongside the main road. The length is 40 miles or so. The earth is used as a return circuit. The line criss-crosses the road at several points, being brought down from the poles and routed through the culverts under the road. No insulators are used. This works pretty well for voice and carrier!

Best regards, Richard Harrison, KB5WZI

well i have used the a99/gpk1 kit for 15 years and it works very well on all of ten meters.i have used it to make contacts all over the planet,at times as a signal is bounced off the f2 it comes back verticle or horizontal so its nice to be able to switch between two antennas.i use it on cw at 28.0 and up and for am,29,0 and fm 29.6 and the repeaters and it works very well.i use it with my icom 756pro11 with the built in tuner and with my mfj-989-c and amp at high power with no problems and the antenna will tune 6 meters but its not to good .73`s Norm:)

I did a quick run with EZNEC, starting with the example file BYDipole, a 20 meter dipole made from #12 wire. Anyone with EZNEC, including the demo version, can duplicate these results.

With copper wire, the maximum field strength is 6.78 dBi. I had to guess at steel, since it varies a great deal, but my guess was a resistivity of 5E-7 ohm-m and relative permeability of 100. With these values, the field strength was 5.0 dB, a 1.78 dB loss. Then I rescaled the length to 3.5 MHz, retaining the #12 wire size. At that length, the field strength with copper wire was 7.04 dBi and with "steel", 4.01. If you've ever tried to get 3 dB of honest gain at 3.5 MHz, you probably won't want to put up with 3 dB of unnecessary loss.

The problem with steel is its permeability. The skin depth is inversely proportional to the square root of permeability, so a relative permeability of 100 decreases the skin depth by a factor of 10, raising the wire resistance by this factor. Zinc, with relative permeability of 1, is a whole lot better, but on typical galvanized fence wire, it's very thin -- probably much less than a skin depth, particularly at low HF, and it does weather off after a while.

If you're after strength, use Copperweld. It gives you the best of both worlds -- the RF conductivity of copper and the strength of steel.

Owen Duffy asked
> Reg, have you thought of adding input fields for rho and mu, so as to
> model gal wire, stainless elements, aluminium etc?
==========
Yes Owen, but decided the amount of interest it would generate and the general usefulness would not be worth the extra effort involved.

Regarding material permeabilty, not surprisingly, manufacturers don't publish permeabilty of magnetic wires which can vary over a magnitude or more depending on alloy. It is not a property of a product which is kept under control. And only 1 in a 1000 even of radio hams show any interest.

It is sufficient to remember the HF resistance of a wire of the same diameter increases in proportion to

Squareroot(R*Mu) relative to copper.

at the same frequency, where R is resistivity relative to copper and Mu is relative permeability.

Incidentally the skin depth increases in exactly the same proportion.

Practical Example. Suppose resistivity is 4 times that of copper and permeabilty is 100 for an alloy of iron. WIre resistance will be Sqrt(4*100) = 20 times that of copper.

Let a copper dipole be a reasonable 97% efficient. 3% of power is lost in the wire. Increase the resistance of the wire by 20 times and about 40% of power will be lost in the wire. This is about 2dB or 1/3 of an S-unit and nobody would ever notice the difference. With a kilowatt, however, the wire would get quite warm. Soon gets rid of ice formations.

You can have a 90-degrees phase difference in the voltage between the ends
of an inductor but the current going into one end must be exactly the same
as comes out of the other in both magnitude and phase.

There's nowhere else for it to go.

Now I suppose somebody will mention parasitic capacitance !

A transmission line has quite a lot of parasitic capacitance. That's why the
input and output currents of a 1/4-wave line differ by 90 dgrees.

Is this little modification what the EH antenna needs to make it work ?

I second Roy`s motion. We used Copperweld in all shortwave broadcast antennas and they didn`t fall. Our rhombics used for reception and temporary transmitting had the longest unsupported wire lengths, but not the largest wire. For the rhombics, the wire used was (3) No.12 wires twisted together, so that it would be flexible enough to work with. These were only rated at 10 KW, so of course we used them at 100 KW.

Source record: 150361

Hi Bill,
excuse me but I am tired to repeat the same long story...I am convinced I can tell you anything you guys want and still you could say me I am a dreamer. I am sure !

For the CFA
please read and print the "stefano's cfa experiment" on the Antennex archive.
Then BUILD IT!!!
I can support you on any problem you may encounter.
After a good construction you will find that efficiency.
The part needs improvements is related to the pattern.
But I am here to help you.

FOR the EH antenna

YOU can't make any judgement simply reading a piece of paper.
YOU must build one of it, THEN you will see...why not?
It costs nothing, you can build it in the your home safe place, what is the risk?
I know is easy criticize, simply because this antenna is not present on any antenna book in the world.
Yes is a big novelty, where is the problem?
the Man's history is full of new discover....why not?

I built a full network eh antenna
I did several installations on the country side , with flat ground, no obstacles
I compared it against a full size dipole, inverted vee , verticals 1/4 with elevated ground radials.
I used professional spectrum analyzer, field stenght meters.
all antennas were perfectely matched with the line . We did all tests to exclude hot lines.
We used baluns, tuned traps, rf transformers to isolate in DC and, at the end, we put the generator BATTERY operated connected directely to the antenna without any piece of coax...no line ok?
During all of these tests the eh antenna produced the same signal strenght of any kind of dipole antenna.

we used a rf source checking for the constant output switching between antennas under test.
any test reported the eh antenna can produce the same efficiency of a dipole.

then we performed a long series of tests ON air.
Months of testing, on different locations . The eh showed a higher s/n

ratio on rx, a very good pattern for dx and local chats.

Bill I think I can continue to the infinity but I am sure you will find
something against, always.
One of the biggest problem is that this developping comes from Italy.
I can understand very well the most common sentence:
" why the world is not full of these antennas? "
Again , many of you make confusion with Cfa. The eh antenna is ready for the
world from the last september.
having such break through novelty takes time to be accepted....is normal we
are not surprised.
In italy there are MANY hams decide to build one of it.
I have a quite long list of ham are transmitting with it.
All of them reported all claims are true.
You are skeptic and is your right, I can understand.
WHAT I can't understand is all this EFFORT to demonstrate the eh antenna
CAN'T work....
why are you so ungry?

You can believe it or not but there is no commercial on my announces. I
would like to share with you this new antenna.
for the first time in the antenna history is not another bended wire.

We decided to reveal all instructions to have one of it built. Why don't you
want test it?
I can't understand... fear? of what?

anyway ,as reported many times, we are developping a 50 and 145 mhz
model....
With these models we could have a professional test on anecoic chamber done.
In that way you will have all numbers, figures and so on....
I keep always my promises.

Ted Hart decided do not answer to all this chorus of polemic.
He will show the AM version when the tests will be over.

Too bad! The very best you can do is to extract 1/2 the available power from an antenna with the perfect match. I`m not sure I should have used the word "available" as that has special significance when used by certain authors.

Best regards, Richard Harrison, KB5WZI

Hi Roy,
I know perfectely the Dr.Trainotti test.
I had with him a long chat via email.

He decided to use some "funny" dimensions for his CFA.
No one Cfa dimension he used was correct...

For me was a comic situation.
Think of calculate a normal dipole lenght / bandwidth using fantasy
formulas....
Roy any antenna MUST follow the right rules...CFA is not an ecception.

he invented all sizes, all proportions...Then the test was
disappointed....:-))) Yes of course !
Dr . Trainotti knows that, I told him that...
he answered me :
" yes Stefano may be could be interesting change some antenna parameters,
but that project is over ,now, I must switch to another project "....
So that test ended with wrong assumptions....

Michele Iz2EAS
I met him at one of the italian EH antenna conference I did.
Michele is teaching at the university on antennas...hence is a very skilled
guy.
is totally skeptic, but on the email you reported you can't understand all
the doubts he got after a long chat with me in front of one EH antenna.

Everybody will remain astonished hearing all the measurable eh antennas
features:

high Bw....more than 400 khz at +- 3db on 40 meters with 1% wav. antenna
NO any warm part in the antenna feeding it with 1 kw without any
coax....where the energy goes??? radiated.We are speaking of 1' and 3"
antenna long!!!!
perfect resistive 50 ohm at the input at mid band
I repeat these are measurable parameters. You just need one of it on hand.

Yes ,of course the indipendent tests...sure ,right.
In the meantime we decided to spread out the concept to allow people
experiment.
I think is honest approach.

The Ringo series of antennas is poorly decoupled from the mast. So a PVC mast is likely to work better than a metal one. If the present configuration is working satisfactorily, leave it alone.

Hi Chip,
How are you??

we had many chats on the CFA antenna. true.
But this new adventure is young, is just born.

Again, you in the USA don't have any idea what in Italy is going on.
There are ham using the eh antenna since the last october.
For one of the rare moments is not the america ONLY leading the way.
Ted decided to stay quiete and silent. he doesn't like the polemics.
I can understand him :-)))

Next february one of the most important ham electronic magazine in Italy
will publish an indipendent test on the eh antenna.
Why?
because a lot of hams requested it....because a lot of hams built it and
experimented it works.
I am sorry In the USA there is no another "stefano" allowing this concept to
be known.

Hi Steve from steve,
Believe me...it doesn't help. Normally nobody wants believe me.

If you want know how build one of it, no problem
If you want to know how tuning it, no problem.
But, then, you should see and decide by your self. I think is the best
approach.

looking on paper only you won't get satisfied. This antenna is a totally
break through.
later ,when you will understand is working, I will be happy to explain you
how it works and why.
sincerly, Stefano Ik5IIR

> Hope this is of some help.

I did think of the control cable also. I bought a few of those RF chokes from Radio Shack last night to experiment with. I put some on the power cable, antenna feedline and the isoloop control cable, but still got into my TV. I also grounded the radio with a strap made from the braid that I cut out of an old piece of coax. I wrapped the other end tightly around the cold water input pipe to the hot water heater next to the radio. I also twisted the antenna and found that on Broadcast tv, I had the minimum amount of TVI (one some channels) when I pointed the edge of the loop directly at the TV.
I also noticed that somoene across the yard was watching tv, so I found my binoculars to look across and transmit a beacon signal and see if I could see any flashing on their screen. They turned off the TV by the time I was ready, so that test failed.

Arrrrgghh! This is frustrating. I hear about people that do this same thing all the time from a condo or apartment, but can't seem to discover the magic arrangement that works!

> The next time I look for a new apartment, what should I look for? ...

Years ago I lucked into an incredible arrangement in an apartment.

I lived in a behemoth apartment complex that was one giant three-story building built around a courtyard with a swimming pool, volleyball courts, etc. The building itself was over a quarter-mile around and had an essentially flat roof.

I somehow managed to talk the management into letting me put antennas on the roof. I made antenna supports by sticking poles in buckets with quick-set concrete. I just dropped the feed lines over the edge and brought them in through the sliding door to the balcony.

I operated a Kenwood TS-120 and eventually a Drake C-Line with good results for the 4 years I lived there.

Hi All,

A follow up from the same antennex site that our friend Stefano so emphatically implores us to visit reveals far more negative reports than the single one quoted above. I won't bore you with reporting the obvious. I am equally sure that Stefano has no answers other than "the dog ate my homework" or responses of similar quality.

These negative reports consist of modeling AND field reports under scientific conditions; and not ad-hoc, jury rigged fumbling so evident in the ONLY data reported from the inventors.

In a nutshell (from another critic):
>There is (in the author's experience) an unbelievably wide divergence
>between the results of our study and the performance claimed
This of course is the conclusion following actual construction and testing and conforms fully with accepted practices and provides no departures from conventional expectations.
We can fully expect Stefano and crowd to reflexively offer to the spirit of:
>
>8. Is the claimant providing an explanation for the observed phenomena
>or merely denying the existing explanation?
>This is a classic debate strategy--criticize your opponent and never
>affirm what you believe to avoid criticism. This stratagem is
>unacceptable in science.

The best that can be said for these air-cooled resistors (in a class with the k2 fractal) is that you don't have to climb a tower to adjust these hyper-critical tuned circuits. What the inventors fail to offer is that if you do hoist this design up a tower, you should first short all elements to achieve near quarterwave performance (provided the tower is quarterwave tall that is).

Source record: 150178

John, while this may appear to be an autotransformer, I think that it might be more instructive to think of it as a tuned circuit inserted perhaps at the base of an antenna or the feedpoint of a wire, and that the tuned circuit has taps that permit a feedline to be connected at an appropriate point for a good match.

Such arrangements are commonly used to feed 1/4 and 1/2-wave verticals, for example, with the coil tuned to resonance for the 1/2 wave use and the cap disconnected for service as a simple loading coil. In either case, the feedline, coax usually, would be connected between the bottom of the coil (braid) and a tap on the coil that gives a desired SWR on the line.

Hi Richard,
I don't know why you are so insistent to find out any reason to prove we are wrong, we are speaking of no science and so on...I am sure all the Ng readers noted your negative mood .
Do you think I am a masochist?
Do you think I have pleasure to spend so many time playing with my name on a world wide Ng?
Do you think I am earning something?
No Richard, I have just the power of the truth.

You are so sure about me, you know all about me, you have perfectely defined what is my thought, what is my target.
I am sorry but my word is equalling your.
Are you the supreme judge?

Your interesting and ,I think, correct scientific american way to weight the claims is like a sword , has two cutting edge.
On the two last yours email I will earn a PASS no a HIT.
because I know where the Dr. Trainotti did the mistake, I know what measures must have a cfa to work, I am not just criticize,I know the answers.I hope you are agree with me this is not the proper site to make a long list of all CFA parameters and how a CFA must be built and tuned...again my word is equalling your.

About Antennex , no sarcasm please. I am a antennex subscriber since 1998.I know very well all the magazine and his editor.

You will laugh stronger ,now, because I must tell you that the Joel analisys is wrong.
BUT also HERE I have all the answers because is wrong (another PASS) . he analyzed the eh like a resonant circuit.
and eh is not. wrong assumptions.Again I can explain all, I can explain why. the day after of the publish, I sent an email to the editor explaining why the columnist was wrong. I motivated it.

The amazing thing is that for you is valid to judge my emails, the antenna , all my claims simply reading some lines on a NG...
I am astonished.
In the other side I am asking the world simply to do what any scentist normally do on his LAB:
"Ok guy you are telling me this antenna is a sort of superman. Then you are providing me all informations how to build it.
I will follow all the instructions. If at the end of the test the antenna is an hoax you will lost any credibility and you must close your mouth for ever. "...

I think this is the correct approach, in the science world , and in THE HAM
world.
The claim is for a new concept, a new application .I think must be
verified.Since is new ,must be understood , needs analysis
No what I am seeing is just sarcasm, irony and condamn
Why don't you make an objective choice?
Why so much energy to convince...who??... the antenna CAN'T work?

But looking at your email it seems you are the JUDGE and I am the
accused....
I am sorry but we are at the same level.

I would love our chats were genuine ,technical, on the antenna....
But to discuss each person must use a good amount of humilty.

Sincerly ,stefano
